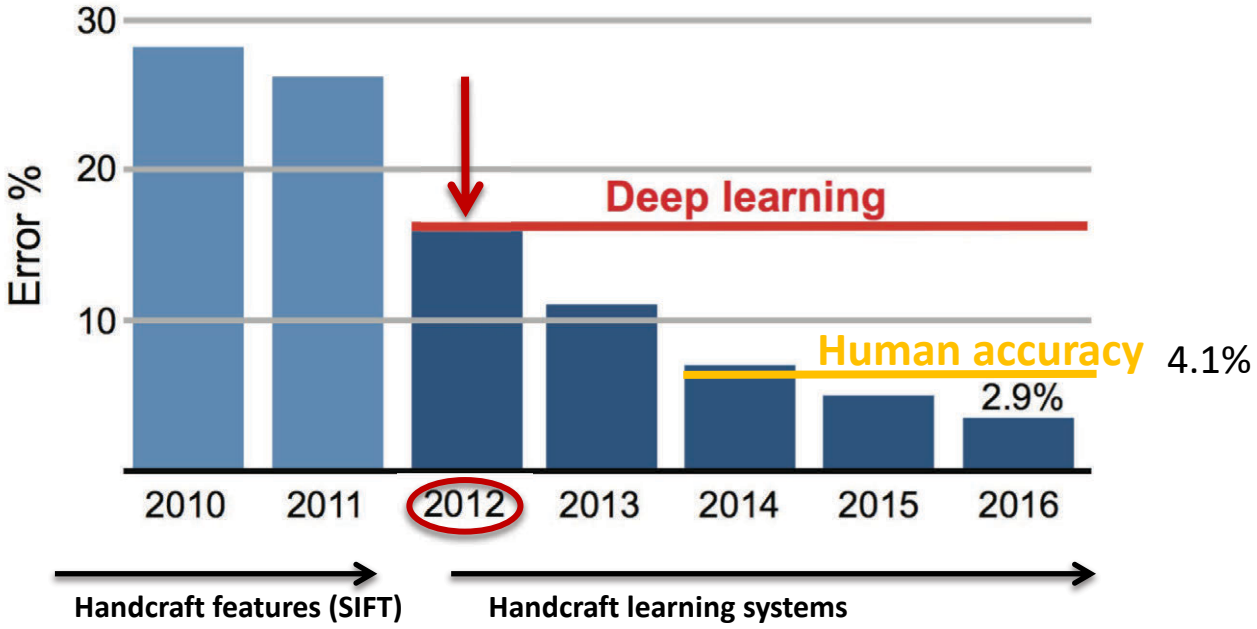
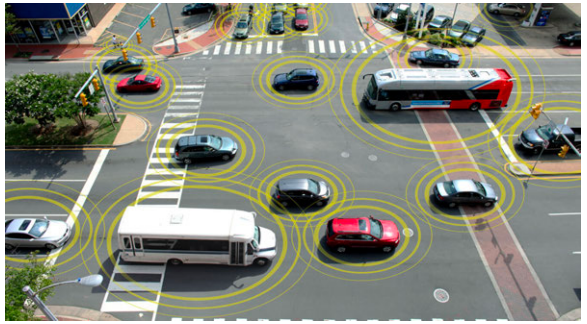
ConvNets

- A breakthrough in Computer Vision :

  LeCun, Bottou, Bengio, Haffner 1998
  Krizhevsky, Sutskever, Hinton, 2012

IMAGENET





- Also in Speech and Natural Language Processing.

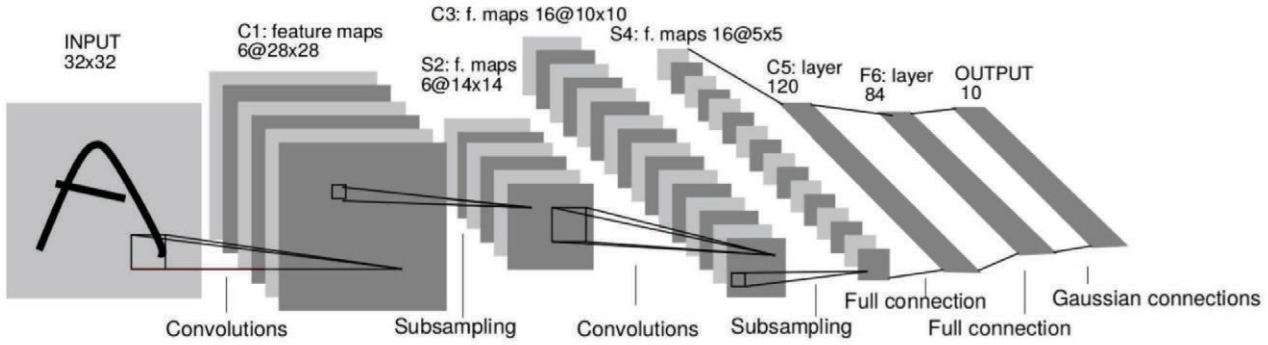
ConvNets

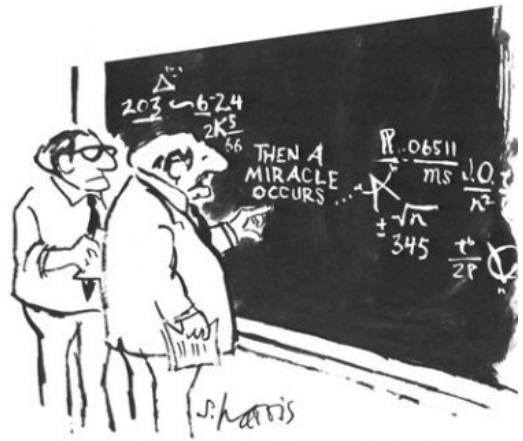
- ConvNets are powerful architectures to solve high-dimensional learning problems.

- Curse of dimensionality :

  dim(image) = 1024 x 1024 ≈ 10^6

  For N=10 samples/dim ⇒ $10^{1,000,000}$ points

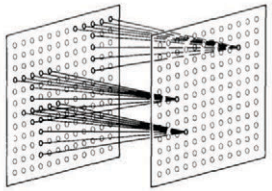


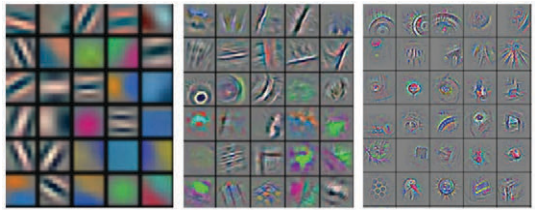


"I think you should be more explicit here in step two."

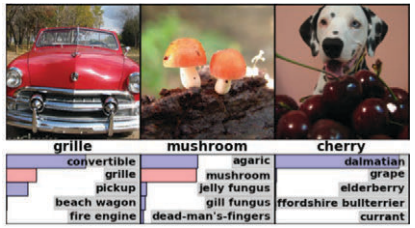
ConvNets

- Main assumption :
  - Data (images, videos, speech) is compositional, it is formed of patterns that are:
    - Local (Hubel-Wiesel 1962)
    - Stationary (shared patterns)
    - Hierarchical (multi-scale)



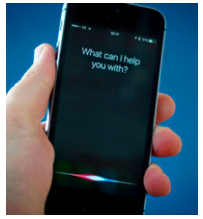


- ConvNets leverage the compositionality structure :
  - They extract compositional features and feed them to classifier, recommender, etc (end-to-end systems).

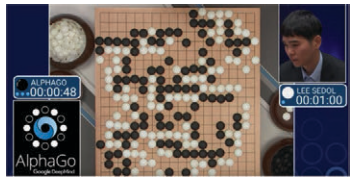


Computer Vision

NLP



Speech



Game of Go

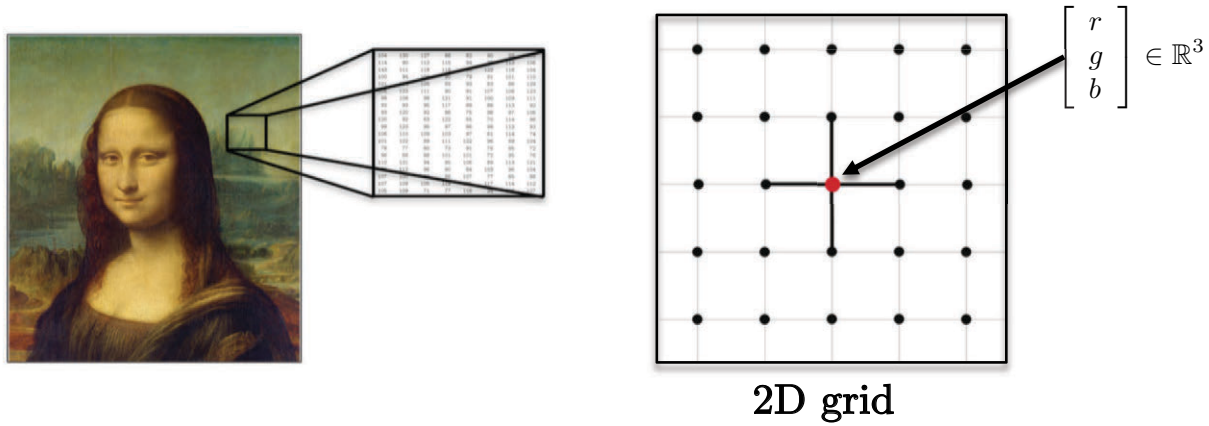
- Conclusion

Data Domain

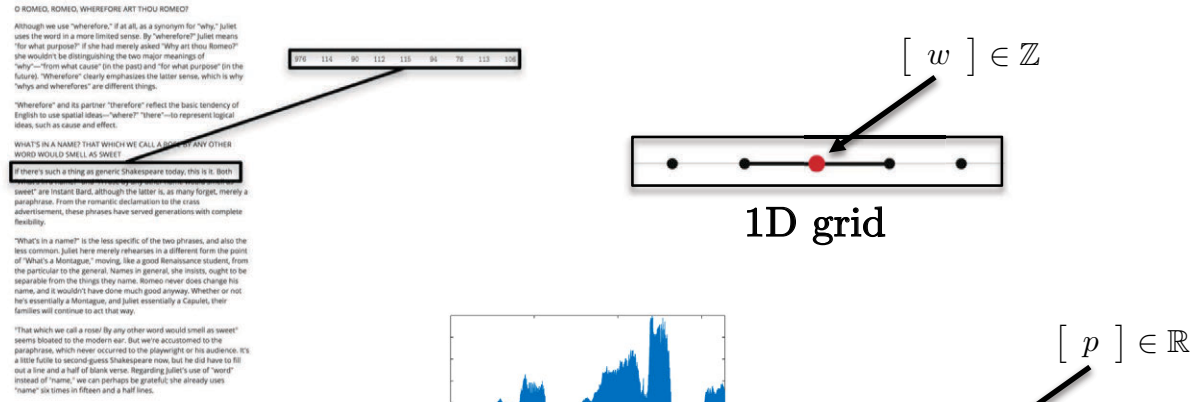
- Images, volumes, videos lie on

  2D, 3D, 2D+1 Euclidean domains (grids)



- Sentences, words, speech lie on

  1D Euclidean domain



- These domains have strong regular spatial structures.
  - All ConvNet operations are mathematically well defined and fast (convolution, pooling).

Convolution

- **Convolutional layer** (for grids) :

$$h^{\ell+1} = w^{\ell} * h^{\ell}$$

$$n_1 \times n_2 \times d \qquad n_1 \times n_2 \times d$$

$$3 \times 3 \times d$$

h^{ℓ}

Image/Hidden features

$*$

w^{ℓ}

Pattern/kernel (learned by backpropagation)

$=$

$h^{\ell+1}$

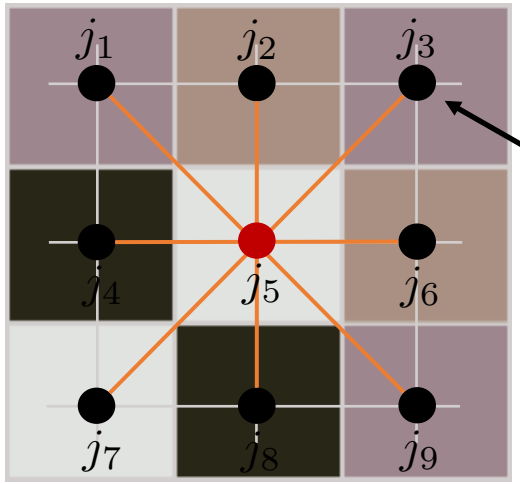
Convolution

- How to define convolution ?
  - Definition #1 : Convolution as template matching
  - O(n) by parallelization and for compact support patterns

$$
\begin{aligned}
h_i^{\ell+1} &= w^\ell * h_i^\ell \\
&= \sum_{\underbrace{j \in \Omega}_{j \in \mathcal{N}_i}} \langle w_j^\ell, \underbrace{h_{i-j}^\ell}_{h_{i+j}^\ell = h_{ij}^\ell} \rangle \\
&= \sum_{j \in \mathcal{N}_i} \langle w_j^\ell, h_{ij}^\ell \rangle \\
&= \sum_{j \in \mathcal{N}_i} \left\langle \begin{bmatrix} w_j^\ell \end{bmatrix}, \begin{bmatrix} h_{ij}^\ell \end{bmatrix} \right\rangle
\end{aligned}
$$

$3 \times 3 \times d$

$n_1 \times n_2 \times d$



All nodes of the template w^l are always ordered/positioned the same way !

w^ℓ

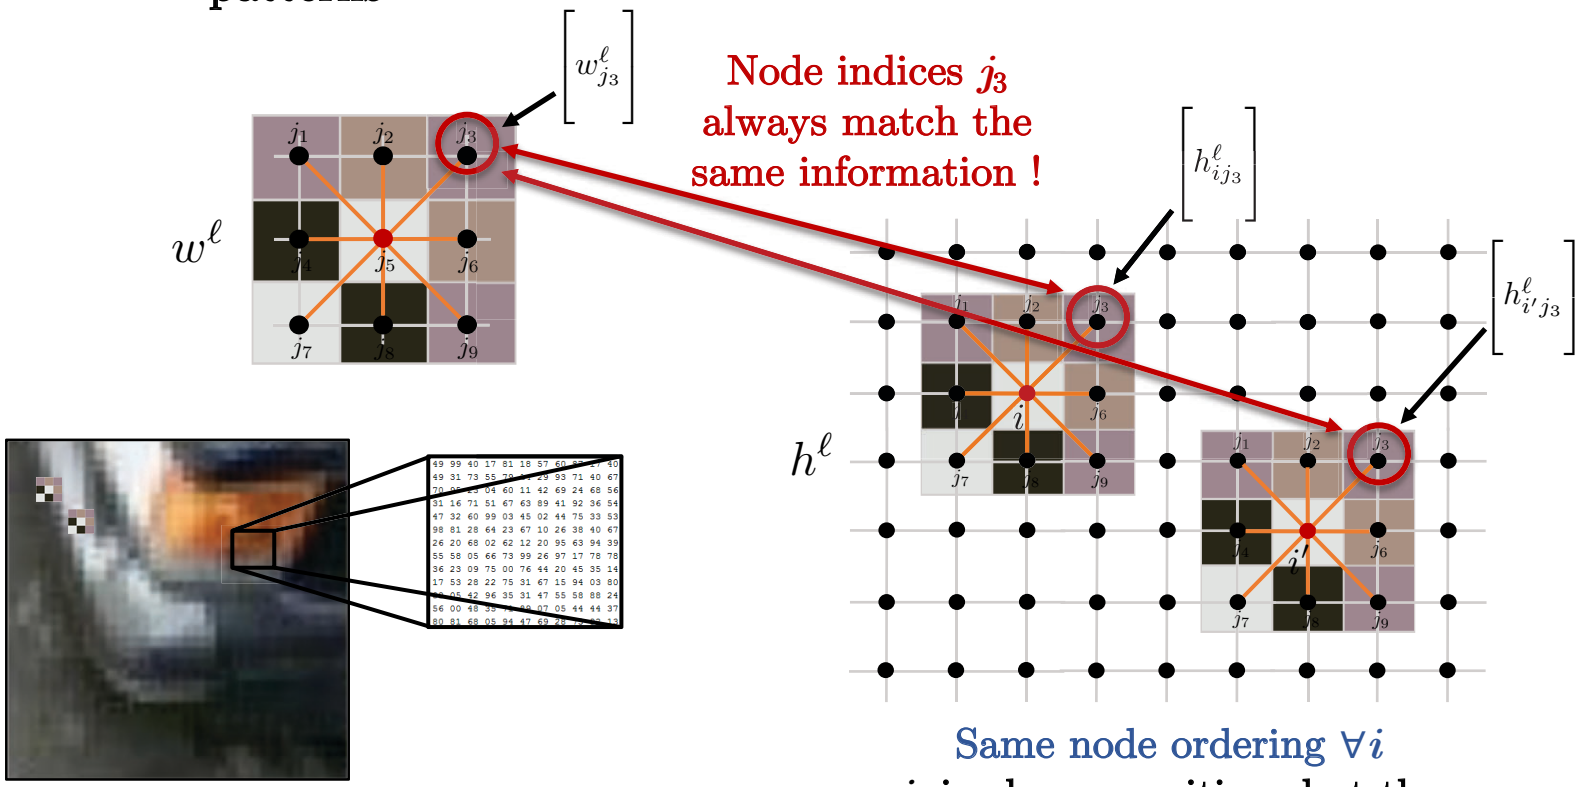
Node j_3 is always located at the top-right corner of the pattern.

$$\begin{bmatrix} w_{j_3}^\ell \end{bmatrix} \in \mathbb{R}^d$$

Template features at j_3

Convolution

- How to define convolution ?
  - Definition #1 : Convolution as template matching
  - O(n) by parallelization for compact support patterns



Same node ordering $\forall i$

j_3 is always positioned at the top-right corner of the template.

$$h_i^{\ell+1} = w^\ell * h_i^\ell$$
$$= \sum_{j \in \mathcal{N}_i} \langle w_j^\ell, h_{ij}^\ell \rangle$$
$$= \sum_{j \in \mathcal{N}_i} \left\langle \begin{bmatrix} w_j^\ell \end{bmatrix}, \begin{bmatrix} h_{ij}^\ell \end{bmatrix} \right\rangle$$

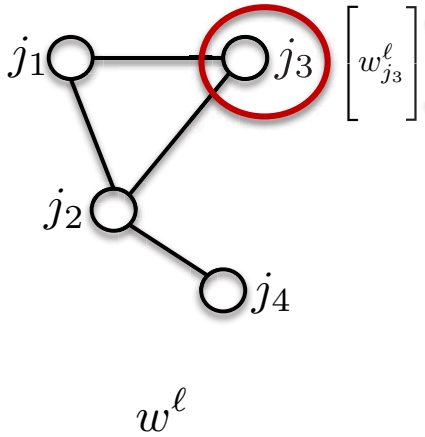
$$\left\langle \begin{bmatrix} w_{j_3}^\ell \end{bmatrix}, \begin{bmatrix} h_{ij_3}^\ell \end{bmatrix} \right\rangle$$

$$\left\langle \begin{bmatrix} w_{j_3}^\ell \end{bmatrix}, \begin{bmatrix} h_{i'j_3}^\ell \end{bmatrix} \right\rangle$$

These matching scores are always for the top-right corner between the template and the image patches.

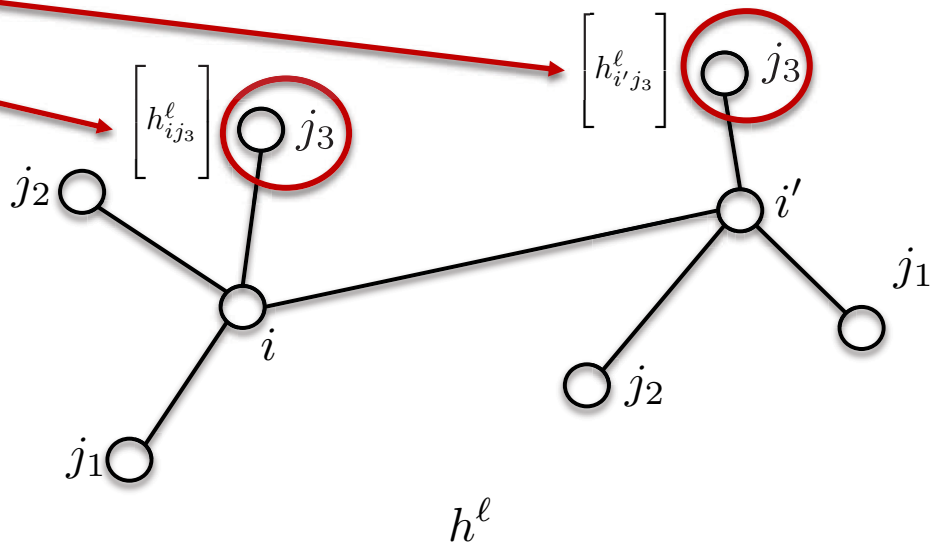
Graph Convolution

- Can we extend template matching for graphs ?
  - Main issues :
    - No node ordering : How to match template features with data features when nodes have no given position (index is not a position) ?



Node j_3 has no specific position. It is just an (arbitrary) index.

Node indices j_3 do not match the same information.



No node ordering on graphs :
The correspondence of nodes is lost on graphs.
There is no up, down, right and left on graphs.

$$\left\langle \begin{bmatrix} w^\ell_{j_3} \end{bmatrix}, \begin{bmatrix} h^\ell_{ij_3} \end{bmatrix} \right\rangle$$

$$\left\langle \begin{bmatrix} w^\ell_{j_3} \end{bmatrix}, \begin{bmatrix} h^\ell_{i'j_3} \end{bmatrix} \right\rangle$$

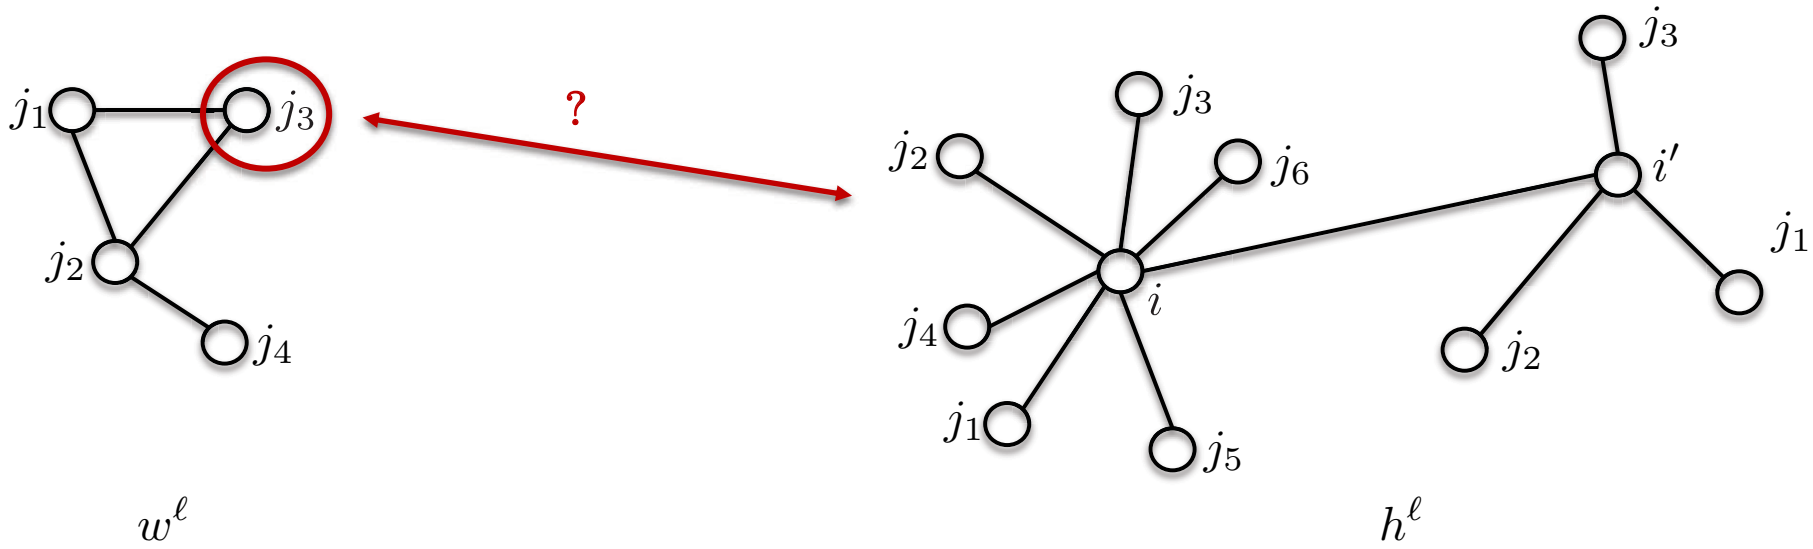
These matching scores have no meaning as they do not compare the same information.

$$h_i^{\ell+1} = w^\ell *_{\mathcal{G}} h_i^\ell = \sum_{j \in \mathcal{N}_i} \langle w_j^\ell, h_{ij}^\ell \rangle$$

$n \times d$

Graph Convolution

- Can we extend template matching for graphs ?
  - Main issues :
    - No node ordering : How to match template features with data features ?
    - Heterogeneous neighborhood : How to deal with different neighborhood sizes ?



Graph Convolution

- How to define convolution ?
  - Definition #1 : Template matching
  - Definition #2 : Convolution theorem
    - Fourier transform of the convolution of two functions is the pointwise product of their Fourier transforms

$$\mathcal{F}(w * h) = \mathcal{F}(w) \odot \mathcal{F}(h) \quad \Rightarrow \quad w * h = \mathcal{F}^{-1}(\mathcal{F}(w) \odot \mathcal{F}(h))$$

    - Generic Fourier transform has $O(n^2)$ complexity, but if the domain is a grid then complexity can be reduced to $O(n \log n)$ with FFT[1].
    - Can we extend the Convolution theorem to graphs ?
      - How to define Fourier transform for graphs ?
      - How to compute fast spectral convolutions in $O(n)$ time for compact kernels ?

$$w *_{\mathcal{G}} h \stackrel{?}{=} \mathcal{F}_{\mathcal{G}}^{-1}(\mathcal{F}_{\mathcal{G}}(w) \odot \mathcal{F}_{\mathcal{G}}(h))$$

[1] JW Cooley, JW Tukey, An algorithm for the machine calculation of complex Fourier series, 1965

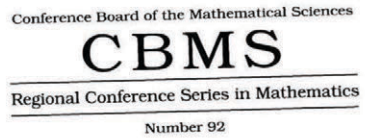
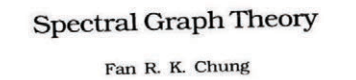
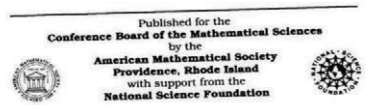
Spectral Convolution

- Spectral graph theory
  - Book of Fan Chung[1] (harmonic analysis, graph theory, combinatorial problems, optimization)



- How to perform spectral convolution ?
  - Graph Laplacian
  - Fourier functions
  - Fourier transform
  - Convolution theorem





[1] FRK Chung, Spectral graph theory, 1997

Graph Laplacian

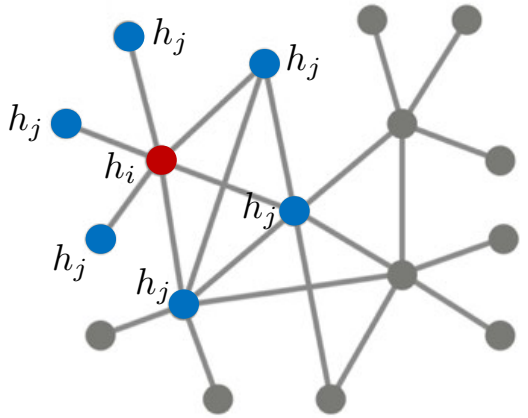
- Core operator in Spectral Graph Theory

$$\mathcal{G} = (V, E, \underset{n \times n}{A}) \quad \rightarrow \quad \underset{n \times n}{\Delta} = \mathrm{I} - D^{-1/2} A D^{-1/2} \qquad \text{Normalized Laplacian}$$

$$\text{where } \underset{n \times n}{D} = \mathrm{diag}(\sum_{j \neq i} A_{ij})$$

- Interpretation :
  - Measure of smoothness : Difference between local value h_i and its neighborhood average values h_j.

$$(\Delta h)_i = h_i - \sum_{j \in \mathcal{N}_i} \frac{1}{\sqrt{d_i d_j}} A_{ij} h_j$$



Fourier Functions

- Eigen-decomposition of graph Laplacian :

Lap Eigenvalues/ Spectrum

Lap Eigenvectors/ Fourier functions

$$\underset{n \times n}{\Delta} = \Phi^T \Lambda \Phi$$

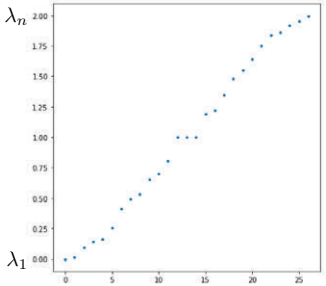
Fourier functions form an orthonormal basis

$$\text{where } \underset{n \times n}{\Phi} = [\phi_1, ..., \phi_n] = \begin{bmatrix} | & & | \\ \phi_1 & ... & \phi_n \\ | & & | \end{bmatrix} \text{ and } \Phi^T \Phi = \mathrm{I}, \ \langle \phi_k, \phi_{k'} \rangle = \delta_{kk'}$$

$$\text{where } \underset{n \times n}{\Lambda} = \mathrm{diag}(\lambda_1, ..., \lambda_n) = \begin{bmatrix} \lambda_1 & & 0 \\ & \ddots & \\ 0 & & \lambda_n \end{bmatrix} \text{ and } 0 \leq \lambda_1 \leq ... \leq \lambda_n = \lambda_{\max} \leq 2$$

$$\text{and } \underset{n \times 1}{\Delta \phi_k} = \lambda_k \phi_k, \quad k = 1, ..., n$$

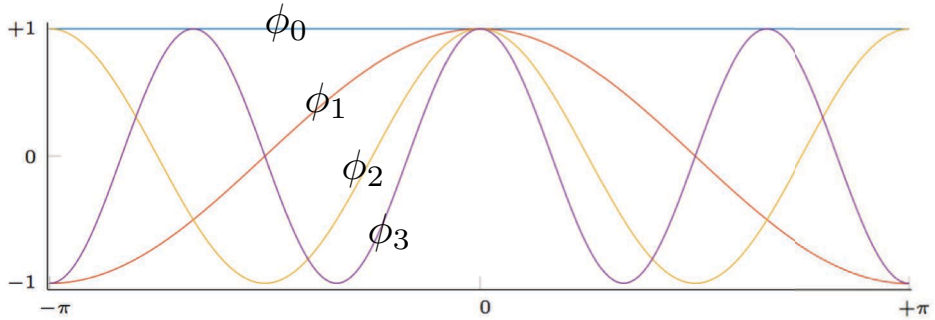
$n = 27$



Spectrum

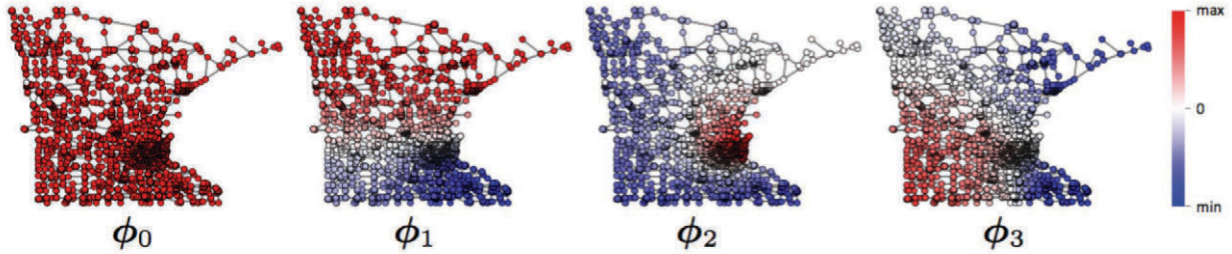
Fourier Functions

- Grid/Euclidean domain :



First eigenvectors of 1D Euclidean Laplacian = standard Fourier basis

- Graph domain :



First Laplacian eigenvectors of a graph

Fourier functions related to graph geometry

(s.a. communities, hubs, etc)

Spectral graph clustering[1]

[1] Von Luxburg, A tutorial on spectral clustering, 2007

Fourier Transform

- Fourier series : Decompose function h with Fourier functions[1] :

$$
\begin{aligned}
\underset{n \times 1}{h} &= \sum_{k=1}^{n} \underbrace{\langle \phi_k, h \rangle}_{\substack{\mathcal{F}(h)_k = \hat{h}_k = \phi_k^T h \\ \text{scalar}}} \underset{n \times 1}{\phi_k} \\
&= \sum_{k=1}^{n} \hat{h}_k \phi_k \\
&= \underbrace{\Phi \hat{h}}_{\mathcal{F}^{-1}(\hat{h})}
\end{aligned}
$$

Fourier transforms are one line of code (linear operations)

$$
\begin{aligned}
\underset{n \times 1}{\mathcal{F}(h)} &= \Phi^T h \\
&= \hat{h} \qquad \text{Fourier Transform/ coefficients of Fourier Series} \\
\underset{n \times 1}{\mathcal{F}^{-1}(\hat{h})} &= \Phi \hat{h} \qquad \text{Inverse Fourier Transform} \\
&= \Phi \Phi^T h = h \text{ as } \mathcal{F}^{-1} \circ \mathcal{F} = \Phi \Phi^T = \mathrm{I} \qquad \text{Orthonormal basis/ Invertible transformation}
\end{aligned}
$$

[1] K. Hammond, P. Vandergheynst, R. Gribonval, Wavelets on graphs via spectral graph theory, 2011

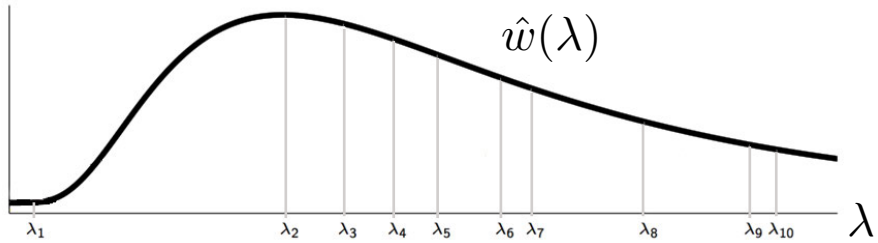
Convolution Theorem

- Fourier transform of the convolution of two functions is the pointwise product of their Fourier transforms :

$$
\begin{aligned}
w * h &= \underbrace{\mathcal{F}^{-1}}_{\Phi}\big(\underbrace{\mathcal{F}(w)}_{\Phi^T w=\hat{w}} \odot \underbrace{\mathcal{F}(h)}_{\Phi^T h}\big) \\
&= \Phi\,(\hat{w} \odot \Phi^T h) \\
&= \Phi\,(\hat{w}(\Lambda)\,\Phi^T h) \\
&= \hat{w}(\underbrace{\Phi\Lambda\Phi^T}_{\Delta})\,h \\
&= \hat{w}(\Delta)h
\end{aligned}
$$

$$
\hat{w} = \begin{bmatrix} \hat{w}(\lambda_1) \\ \vdots \\ \hat{w}(\lambda_n) \end{bmatrix}
$$

$$
\hat{w}(\Lambda) = \mathrm{diag}(\hat{w}) = \begin{bmatrix} \hat{w}(\lambda_1) & & 0 \\ & \ddots & \\ 0 & & \hat{w}(\lambda_n) \end{bmatrix}
$$



Expensive computation $O(n^2)$

No FFT

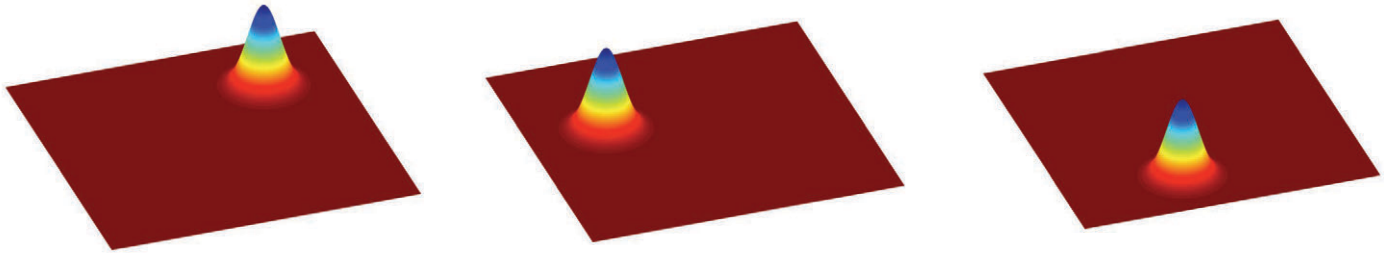
Spectral function/filter

No Shift Invariance for Graphs

- A signal h on graph can be translated to vertex i as follows :

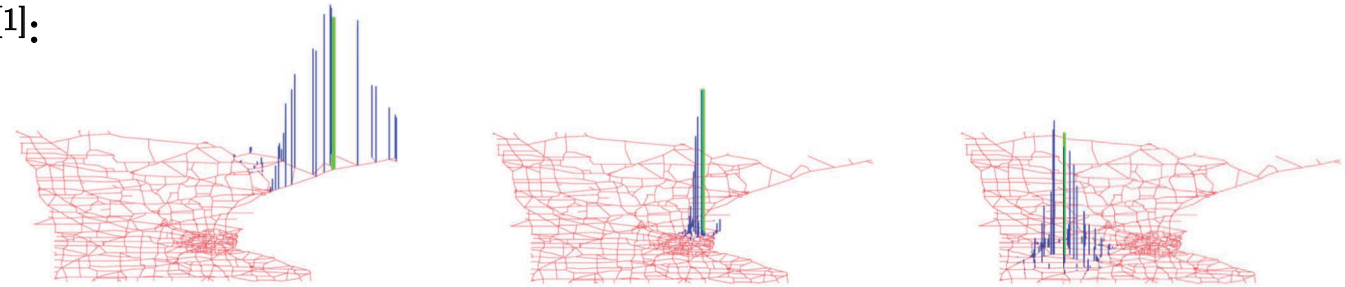
$$\mathrm{T}_i h = \delta_i * h$$

- Grid/Euclidean domain :



$\mathrm{T}_i h$ $\mathrm{T}_{i'} h$ $\mathrm{T}_{i''} h$

- Graph domain[1]:



$\mathrm{T}_i h$ $\mathrm{T}_{i'} h$ $\mathrm{T}_{i''} h$

[1] K. Hammond, P. Vandergheynst, R. Gribonval, Wavelets on graphs via spectral graph theory, 2011

Outline

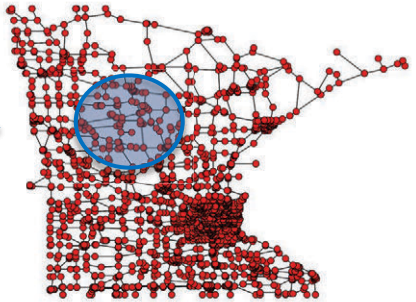
- Part 1: Traditional ConvNets
  - Architecture
  - Graph Domain
  - Convolution
- **Part 2: Spectral Graph ConvNets**
  - Spectral Convolution
  - **Spectral GCNs**
- Part 3: Spatial Graph ConvNets
  - Template Matching
  - Isotropic GCNs
  - Anisotropic GCNs
  - Lab on GatedGCNs
- Part 4: Benchmarking Graph Neural Networks
- Conclusion

Vanilla Spectral GCN[1]

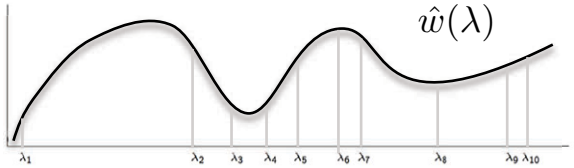
- Graph spectral convolutional layer :

$$
\begin{aligned}
\underset{n \times d}{h^{\ell+1}} &= \eta(\ w^{\ell} * h^{\ell}\ ) \\
&= \eta(\ \hat{w}^{\ell}(\Delta) h^{\ell}\ ) \\
&= \eta(\ \underset{n \times n}{\Phi \hat{w}^{\ell}(\Lambda) \Phi^{T}} \underset{n \times d}{h^{\ell}}\ )
\end{aligned}
$$

Spatial filter



Spectral filter



- First spectral technique for ConvNets
- Limitations :
  - No guarantee of spatial localization of filters
  - O(n) parameters to learn per layer
  - O(n^2) learning complexity (Fourier transform with full matrix ϕ)

$$
\hat{w}(\Lambda) = \begin{bmatrix} \hat{w}(\lambda_1) & & 0 \\ & \ddots & \\ 0 & & \hat{w}(\lambda_n) \end{bmatrix}
$$

[1] Bruna, Zaremba, Szlam, LeCun, Spectral Networks and Locally Connected Networks on Graphs, 2014

SplineGCNs[1,2]

- Graph spectral convolutional layer :

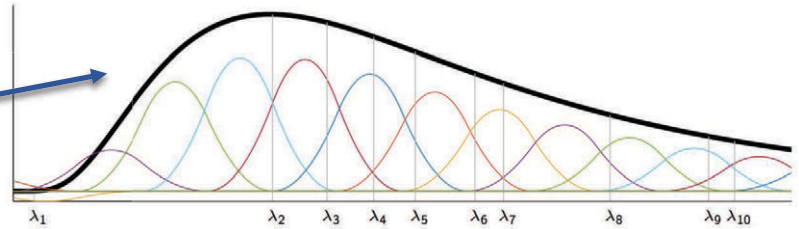
$$h^{\ell+1}_{n\times d} = \eta(\ w^\ell * h^\ell\ )$$
$$= \eta(\ \Phi \hat{w}^\ell(\Lambda)\Phi^T h^\ell\ )$$
$$\hat{w}^\ell(\Lambda)_{n\times n} = \mathrm{diag}(B w^\ell)$$

$K \times 1$

$n \times K$

$n \times n$

Smooth spectral filters



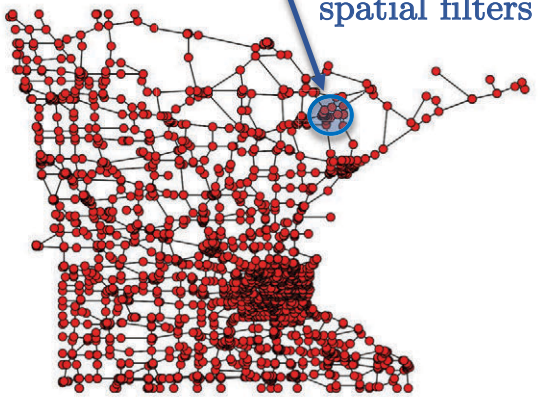
The K coefficients w^l are learned by backpropagation

Smooth spectral filters/
Linear combination of K smooth kernels B (splines)

Parseval's Identity
Localization in space ⇔
Smoothness in frequency domain
(Heisenberg's uncertainty principle)

$$\int |x|^{2k}|w(x)|^2 dx = \int |\frac{\partial^k \hat{w}(\lambda)}{\partial \lambda^k}|^2 d\lambda$$

Localized spatial filters



- Localized filters in space (fast-decaying)
- O(*1*) parameters to learn per layer
- O(n^2) learning complexity (Fourier transform with full matrix ϕ)

[1] Bruna, Zaremba, Szlam, LeCun, Spectral Networks and Locally Connected Networks on Graphs, 2014
[2] Henaff, Bruna, LeCun, Deep Convolutional Networks on Graph-Structured Data, 2015

LapGCNs[1]

- How to learn in linear time $O(n)$ (w.r.t. graph size n) ?
  - $O(n^2)$ complexity comes from the direct use of Laplacian eigenvectors :

$$\underset{n \times d}{O(w * h)} = \underset{n \times n}{O(\Phi} \underset{n \times n}{\hat{w}^{\ell}(\Lambda)} \underset{n \times d}{\Phi^T h)} = O(n^2)$$

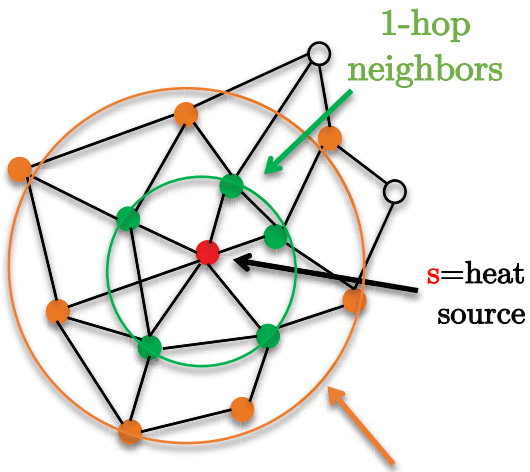
Full matrix

- How to avoid the eigen-decomposition ?
  - Learn directly functions of the Laplacian !

$$w * h = \hat{w}(\Delta) h$$

$$\underset{n \times n}{\hat{w}(\Delta)} = \sum_{k=0}^{K-1} w_k \underset{n \times n}{\Delta^k}$$

Coefficients w_k are learned by backpropagation.



Filters are exactly localized in k-hop supports.
(each Laplacian operation increases the support of a function by 1 hop)

[1] Defferrard, Bresson, Vandergheynst, Convolutional neural networks on graphs with fast localized spectral filtering, 2016

LapGCNs

- Learning complexity :

$$
\begin{aligned}
w * h &= \hat{w}(\Delta)h \\
&= \sum_{k=0}^{K-1} w_k \Delta^k h \\
&= \sum_{k=0}^{K-1} w_k X_k, \text{ with } \underset{n \times n}{X_k} = \Delta \underset{n \times d}{X_{k-1}} \text{ and } \underset{n \times d}{X_0} = h
\end{aligned}
$$

Recursive equation

- Sequence $\{X_k\}$ is generated by multiplying a matrix Δ and a vector X_{k-1} ⇒ Complexity is O(E.K)=O(n) for sparse (real-world) graphs.
- No eigen-decomposition of Laplacian (ϕ,Λ) was required.
  - The name spectral GCNs can be misguided as the Lap eigen-decomposition is not used (computations are done in the spatial domain, not the spectral domain).
- Graph convolutional layers are (sparse) linear operations, thus GPU friendly (but not yet optimized).

LapGCNs

- Implementation :

$$
\begin{aligned}
\underset{n \times d}{h^{\ell+1}} &= \eta\Big(\sum_{k=0}^{K-1} \underset{n \times n}{w_k^\ell} \underset{n \times d}{\Delta^k h^\ell} \Big) \\
&= \eta\Big(\sum_{k=0}^{K-1} w_k^\ell \underset{n \times d}{X_k} \Big) \\
&= \eta\Big(\underbrace{(w^\ell)^T \bar{X}}_{\text{reshape}} \Big) \\
&\qquad\qquad \underset{n \times d}{}
\end{aligned}
$$

$$
\underset{K \times nd}{\text{with } \bar{X}} = \begin{bmatrix} - & \bar{X}_0 & - \\ & \vdots & \\ - & \bar{X}_{K-1} & - \end{bmatrix}
$$

$$
\underset{1 \times nd}{\bar{X}_k} = \underset{n \times d}{\text{reshape}(X_k)}
$$

$$
\underset{K \times 1}{w^\ell} = \begin{bmatrix} w_0^\ell \\ \vdots \\ w_{K-1}^\ell \end{bmatrix}
$$

- Filters are exactly localized in K-hop support
- O(*1*) parameters to learn per layer
- O(n) learning complexity
- Monomials basis are unstable under coefficients perturbation (hard to optimize)

$$
1, x, x^2, x^3, \ldots \quad \rightarrow \quad \Delta^0, \Delta^1, \Delta^2, \Delta^3, \ldots
$$

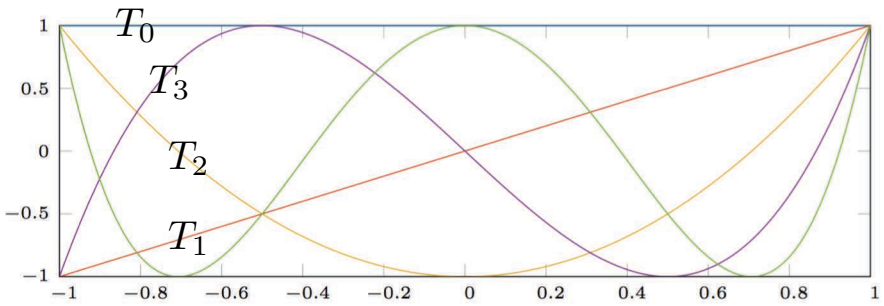
Chebyshev Polynomials

- Graph spectral convolution with Chebyshev polynomials :

$$
\begin{aligned}
w * h &= \hat{w}(\Delta)h \\
&= \sum_{k=0}^{K-1} w_k T_k(\Delta)h \\
&= \sum_{k=0}^{K-1} w_k X_k, \text{ with } X_k = 2\tilde{\Delta}X_{k-1} - X_{k-2}, X_0 = h, X_1 = \tilde{\Delta}h \text{ and } \tilde{\Delta} = 2\lambda_n^{-1}\Delta - \mathrm{I}
\end{aligned}
$$

Recursive equation

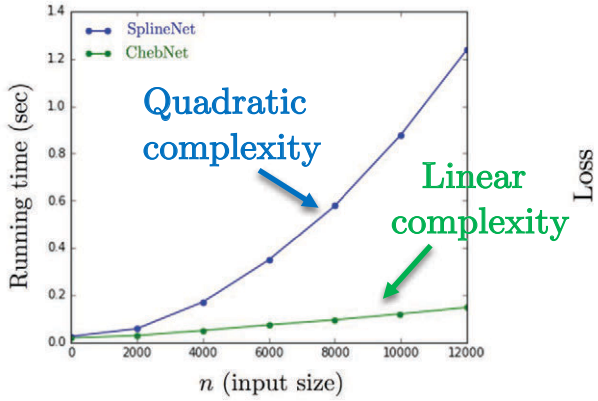
- Filters are exactly localized in K-hop support
- O(*1*) parameters to learn per layer
- O(n) learning complexity
- Stable under coefficients perturbation



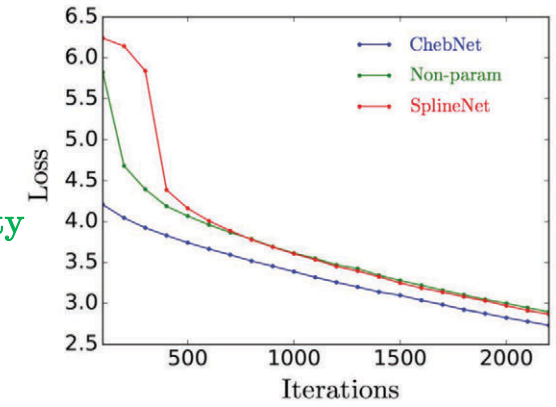
Orthonormal basis

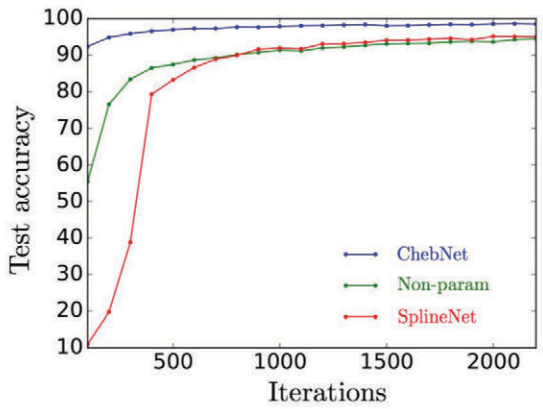
MNIST Numerical Experiment[1]

Running time



Optimization





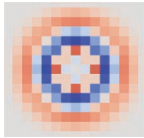
Accuracy

Model	Order	Accuracy
LeNet5	-	99.33%
SplineNet	25	97.75%
ChebNet	25	99.14%

- ChebNets :
  - ConvNets for arbitrary graph domains
  - Same O(n) learning complexity (but larger complexity constant)
  - Limitation : Isotropic model

- Isotropy vs anisotropy
  - Standard ConvNets produce anisotropic filters because Euclidean grids have directional structures (up, down, left, right).

  - Spectral ConvNets like ChebNets compute isotropic filters because there is no notion of directions on arbitrary graphs.



[1] Defferrard, Bresson, Vandergheynst, Convolutional neural networks on graphs with fast localized spectral filtering, 2016

ChebNets for Multiple Graphs

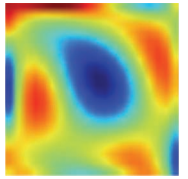
- Multi-graph spectral convolution[1] :

$$\underset{n_1 \times n_2 \times d}{h^{\ell+1}} = \eta\Big(\hat{w}(\Delta_1, \Delta_2) * h^{\ell} \Big)$$

$$h^{\ell+1} = \eta\Big(\sum_{k_1=0}^{K_1-1} \sum_{k_2=0}^{K_2-1} \underset{K_1 \times K_2}{w_{k_1,k_2}} \underset{n_1 \times n_1}{T_{k_1}(\Delta_1)} \underset{n_2 \times n_2}{T_{k_2}(\Delta_2)} h^{\ell} \Big)$$

$$\underset{n_1 \times n_2}{\hat{w}(\lambda_1, \lambda_2)} = \sum_{k_1=0}^{K_1-1} \sum_{k_2=0}^{K_2-1} w_{k_1,k_2} T_{k_1}(\Lambda_1) T_{k_2}(\Lambda_2)$$

2D Spectral filter

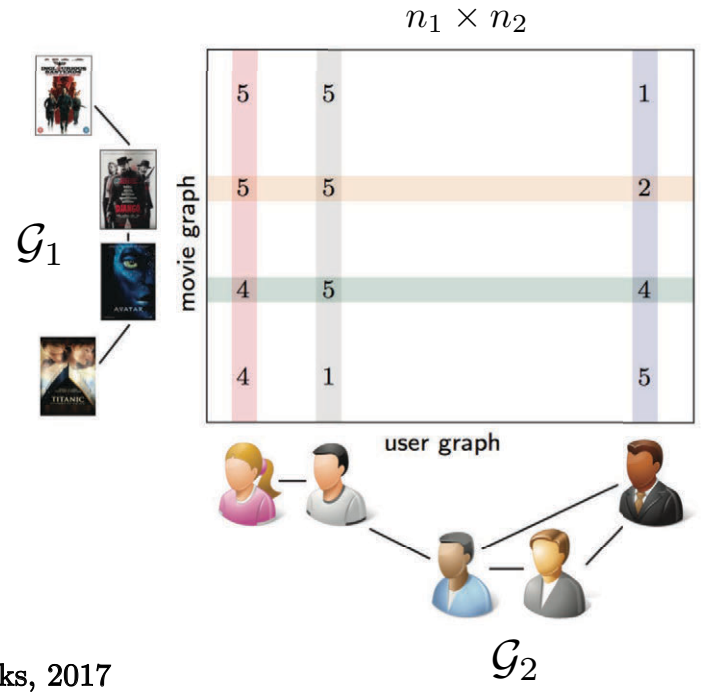


$\hat{w}(\lambda_1, \lambda_2)$

The $K_1.K_2$ coefficients $w_{k1,k2}$ are learned by backpropagation.

- Recommendation task (Netflix)
  - Matrix Completion with Multiple Graphs[2] :

$$\min_{h \in \mathbb{R}^{n_1 \times n_2}} \quad \|h\|_* + \mu \|\Omega \circ (h - r)\|_{\mathrm{F}}^2 + \mu_1 \underbrace{\mathrm{tr}(h \Delta_1 h^\top)}_{\|h\|_{\mathcal{G}_1}^2} + \mu_2 \underbrace{\mathrm{tr}(h^\top \Delta_2 h)}_{\|h\|_{\mathcal{G}_2}^2}$$



[1] F Monti, M Bronstein, X Bresson, Geometric matrix completion with recurrent multi-graph neural networks, 2017
[2] V Kalofolias, X Bresson, M Bronstein, P Vandergheynst, Matrix completion on graphs, 2014

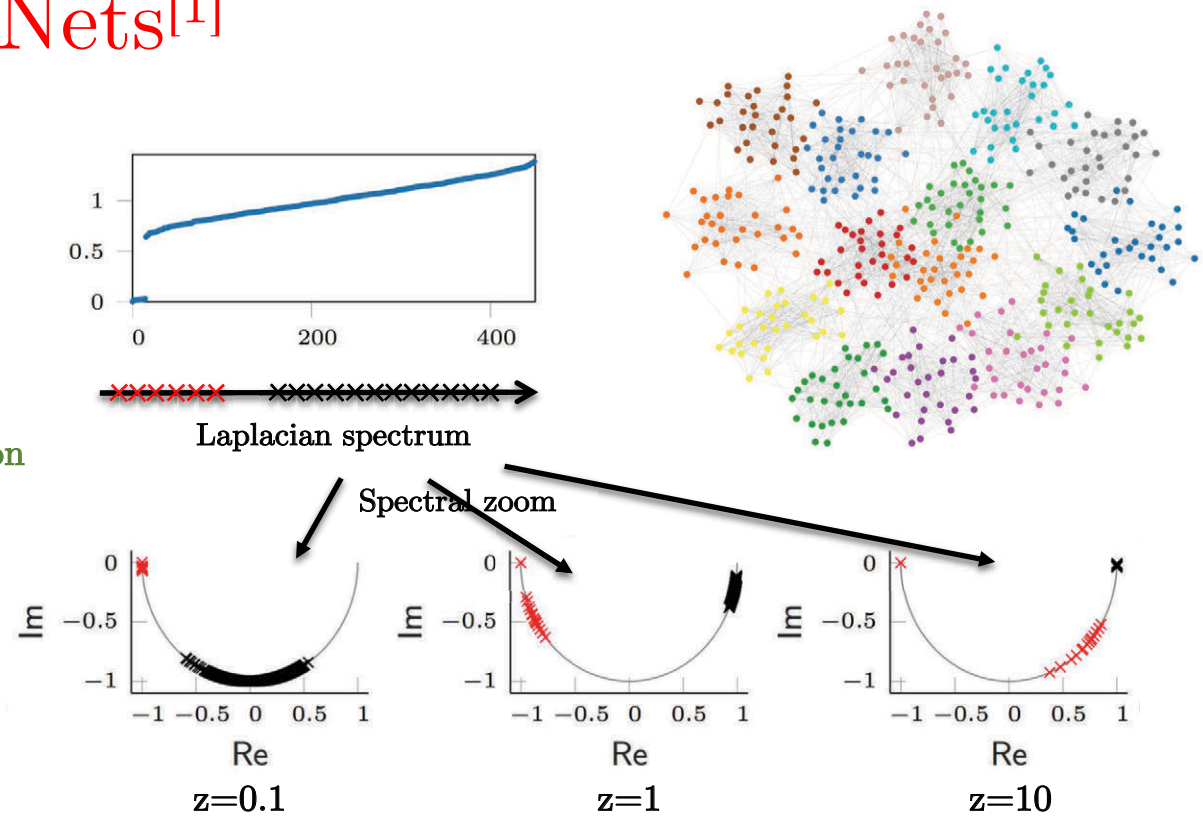
CayleyNets[1]

- ChebGCNs are unstable to produce filters with frequency bands of interest (graph communities).
- Cayley rationals can :

Spectral zoom z focuses on frequency bands.

$$\hat{w}(\Delta) = w_0 + 2\mathrm{Re}\{\sum_{k=0}^{K-1} w_k \frac{(z\Delta - i)^k}{(z\Delta + i)^k}\}$$

The K coefficients w_k are learned by backpropagation.



- CayleyNets
  - Same properties as ChebNets
  - Localized in frequency (with spectral zoom)
  - Richer class of filters for the same order K
  - Isotropic model

[1] R Levie, F Monti, X Bresson, MM Bronstein, CayleyNets: Graph convolutional neural networks with complex rational spectral filters, 2018

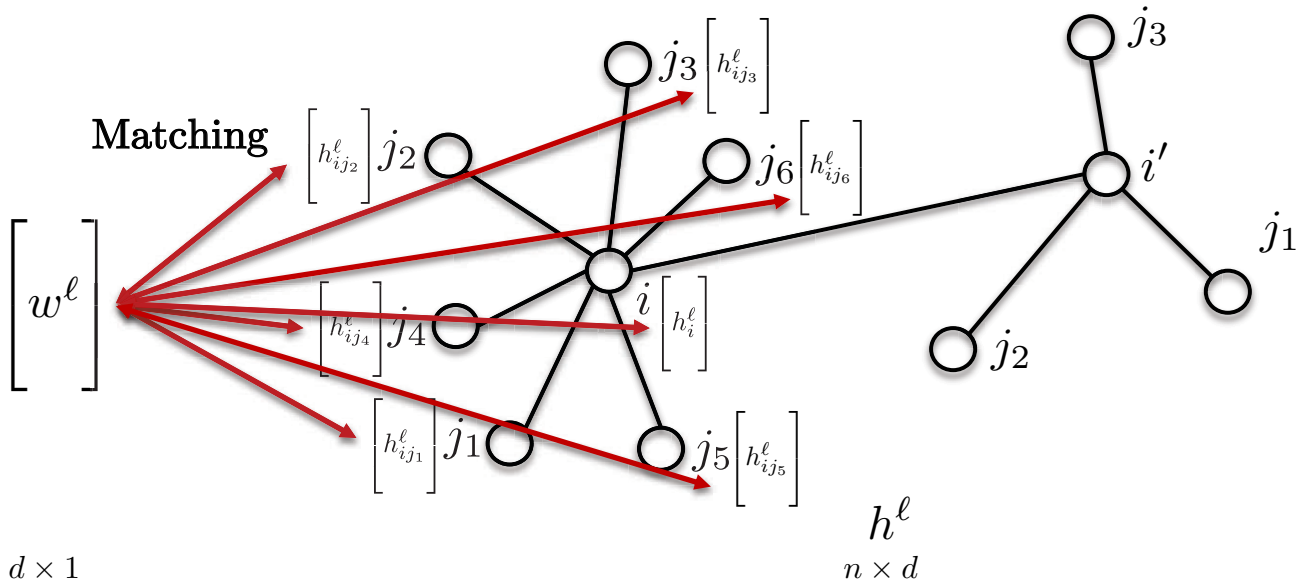
- Conclusion

Template Matching

- How to define template matching for graphs ?
  - Main issue is the absence of node ordering/positioning.
    - Node indices are arbitrary and do not match the same information.
  - How to design template matching invariant to node re-parametrization ?
    - Simply use the same template features for all neighbors !



$$\underset{\text{scalar}}{h_i^{\ell+1}} = \eta\Big(\sum_{j \in \mathcal{N}_i} \underbrace{\underset{d \times 1}{\langle w^\ell, h_{ij}^\ell \rangle}}_{(h_{ij}^\ell)^T w^\ell} \Big) \quad \underset{d \times 1}{}$$

One feature

$$\underset{d \times 1}{h_i^{\ell+1}} = \eta\Big(\sum_{j \in \mathcal{N}_i} \underset{d \times d}{W^\ell} \underset{d \times 1}{h_{ij}^\ell} \Big)$$

***d* features**

$$\underset{n \times d}{h^{\ell+1}} = \eta\Big(\underset{n \times n}{A} \underset{n \times d}{h^\ell} \underset{d \times d}{W^\ell} \Big)$$

  - Template Matching
  - **Isotropic GCNs**
  - Anisotropic GCNs
  - Lab on GatedGCNs
- Part 4: Benchmarking Graph Neural Networks
- Conclusion

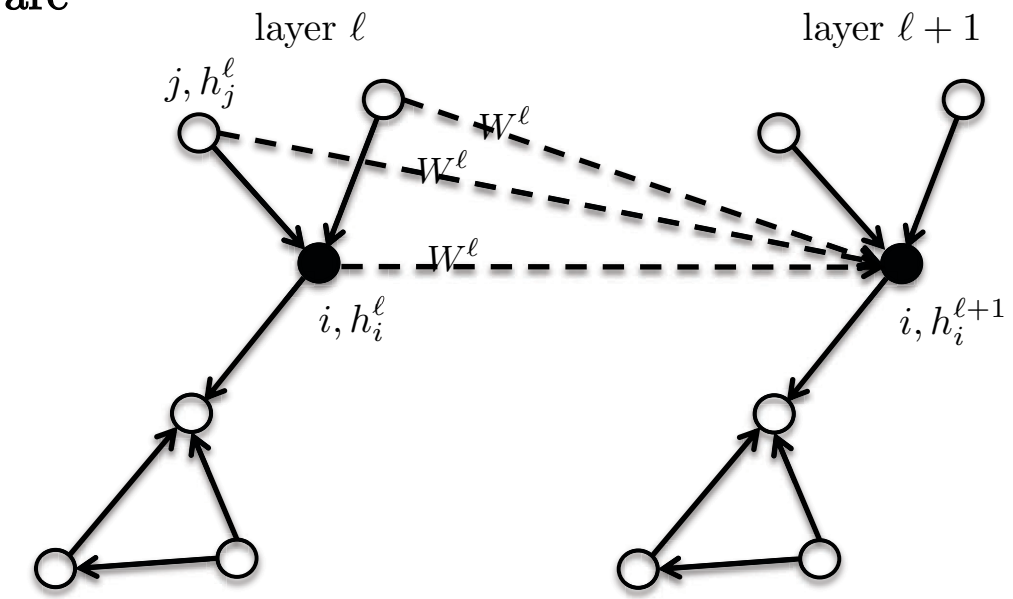
Vanilla GCNs[1,2,3]

- Simplest formulation of spatial GCNs
  - Handle the absence of node ordering
    - Invariant by node re-parametrization
  - Deal with different neighborhood sizes
  - Local reception field by design (only neighbors are considered)
  - Weight sharing (convolution property)
  - Independent of graph size
  - Limited to isotropic capability

$$\underset{n \times d}{h^{\ell+1}} = \eta(\overset{n \times n}{D^{-1}} \overset{n \times n}{A} \overset{n \times d}{h^{\ell}} \underset{d \times d}{W^{\ell}}) \quad \text{Matrix representation}$$

$$\underset{d \times 1}{h_i^{\ell+1}} = \eta(\underbrace{\frac{1}{d_i}}_{\text{scalar}} \sum_{j \in \mathcal{N}_i} A_{ij} \underset{d \times d}{W^{\ell}} \underset{d \times 1}{h_j^{\ell}}) \quad \text{Vectorial representation}$$

Mean



$$h_i^{\ell+1} = f_{\text{GCN}}(h_i^\ell, \{h_j^\ell : j \to i\})$$

[1] Scarselli, Gori, Tsoi, Hagenbuchner, Monfardini, The Graph Neural Network Model, 2009
[2] TN Kipf, M Welling, Semi-supervised classification with graph convolutional networks, 2016
[3] S Sukhbaatar, A Szlam, R Fergus, Learning multiagent communication with backpropagation, 2016

ChebNets[1] and Vanilla GCNs[2,3]

- Vanilla GCNs is a simplification of ChebNets.
  - Truncated expansion of Chebyshev spectral convolution :

$$
\begin{aligned}
h^{\ell+1} &= \eta(\ w^{\ell} * h^{\ell}\ ) \\
&= \eta(\ \hat{w}^{\ell}(\Delta) h^{\ell}\ ) \\
&= \eta(\ \sum_{k=0}^{K-1} w_k^{\ell} T_k(\Delta) h^{\ell}\ )
\end{aligned}
$$

Suppose $K = 2,\ w_0^{\ell} = w^{\ell},\ w_1^{\ell} = -w^{\ell},\ \lambda_n = 2,$

$$
\begin{aligned}
h^{\ell+1} &= \eta(\ w^{\ell}(T_0(\Delta) - T_1(\Delta)) h^{\ell}\ ) \\
&= \eta(\ w^{\ell}(\mathrm{I} + D^{-1/2} A D^{-1/2}) h^{\ell}\ )
\end{aligned}
$$

Operator with largest eigenvalue in [0,2] may cause divergence.

Add self-loop to graphs $\hat{A} = A + \mathrm{I}$

$$
\begin{aligned}
h^{\ell+1} &= \eta(\ w^{\ell} \hat{D}^{-1/2} \hat{A} \hat{D}^{-1/2} h^{\ell}\ ) \quad \text{(single feature)} \\
&= \eta(\ \hat{D}^{-1/2} \hat{A} \hat{D}^{-1/2} h^{\ell} W^{\ell}\ ) \quad (d \text{ features}) \\
h_i^{\ell+1} &= \eta(\ \frac{1}{\hat{d}_i^{-1/2}} \sum_{j \in \mathcal{N}_i} \frac{1}{\hat{d}_j^{-1/2}} \hat{A}_{ij} W^{\ell} h_j^{\ell}\ )
\end{aligned}
$$

with

$$
\begin{cases}
T_0 = I \\
T_1 = \tilde{\Delta} = \dfrac{2}{\lambda_n} \Delta - \mathrm{I} \overset{\lambda_n = 2}{=} \Delta - I \\
\Delta = \mathrm{I} - D^{-1/2} A D^{-1/2}
\end{cases}
$$

GraphSage[1]

- Vanilla GCNs (supposing $A_{ij} = 1$) : $h_i^{\ell+1} = \eta\left(\frac{1}{d_i} \sum_{j \in \mathcal{N}_i} W^\ell h_j^\ell \right)$
- GraphSage :
  - Differentiate template weights W^l between neighbors h_j and central node h_i.
  - Isotropic GCNs

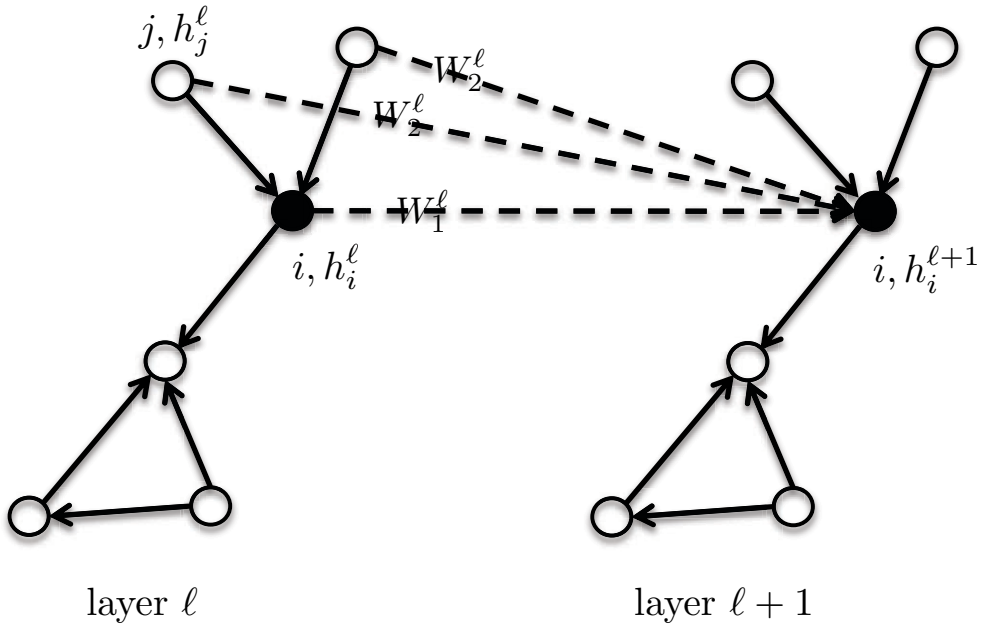
$$\underset{d \times 1}{h_i^{\ell+1}} = \eta\Big(\underset{d \times d}{W_1^\ell} \underset{d \times 1}{h_i^\ell} + \underbrace{\frac{1}{d_i} \sum_{j \in \mathcal{N}_i} \underset{d \times d}{W_2^\ell} \underset{d \times 1}{h_j^\ell}} \Big)$$

$\text{Mean}_{j \in \mathcal{N}_i} \; W_2^\ell h_j^\ell$

Or alternatively,

$\text{Max}_{j \in \mathcal{N}_i} \; W_2^\ell h_j^\ell$

$\text{LSTM}^\ell(h_j^\ell)$



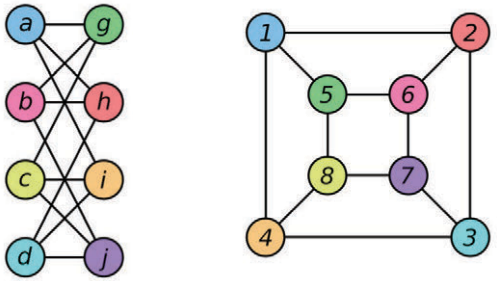
[1] W Hamilton, Z Ying, J Leskovec, Inductive representation learning on large graphs, 2017

Graph Isomorphism Networks[1] (GIN)

- Architecture that can differentiate graphs that are not isomorphic.
  - Graph isomorphism is an equivalent relation for similar graph structures.

- Isotropic GCNs

$$h_i^{\ell+1} = \underset{d\times 1}{\mathrm{ReLU}}\Big(\underset{d\times d}{W_2^{\ell}}\ \mathrm{ReLU}\Big(\ \underbrace{\mathrm{BN}}_{\text{Batch normalization}}\Big(\underset{d\times d}{W_1^{\ell}}\underset{d\times 1}{\hat{h}_i^{\ell+1}}\Big)\ \Big)\Big)$$
$$\hat{h}_i^{\ell+1} = (1+\epsilon)\, h_i^{\ell} + \sum_{j\in\mathcal{N}_i} h_j^{\ell}$$



Example of two isomorphic graphs

[1] K Xu, W Hu, J Leskovec, S Jegelka, How powerful are graph neural networks?, 2018

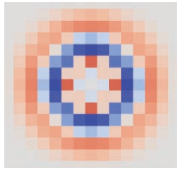
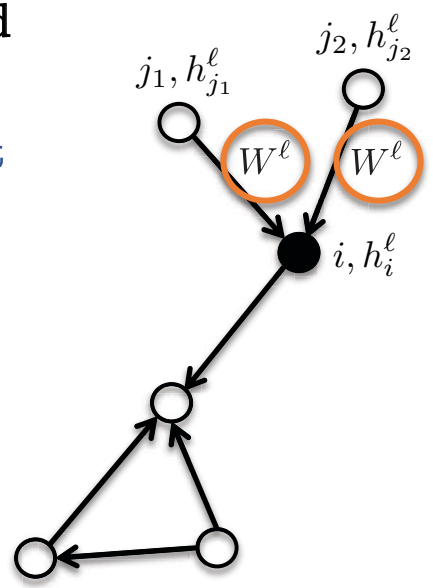
  - Lab on GatedGCNs
- Part 4: Benchmarking Graph Neural Networks
- Conclusion

Anisotropic GCNs

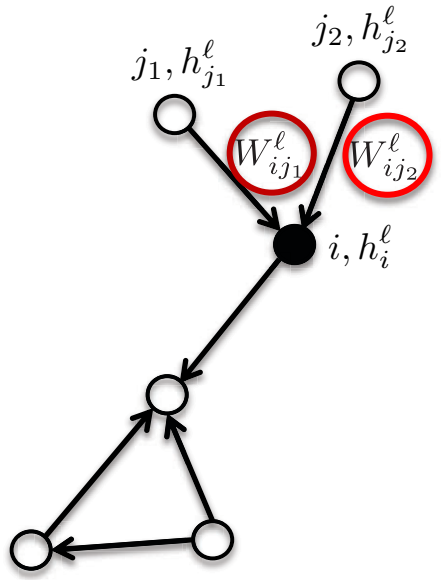
- Reminder :
  - Standard ConvNets produce anisotropic filters because Euclidean grids have directional structures (up, down, left, right).
  - GCNs such as ChebNets, CayleyNets, Vanilla GCNs, GraphSage, GIN compute isotropic filters as there is no notion of directions on arbitrary graphs.



- How to get anisotropy back in GNNs ?
  - Natural edge features[1,2] if available (e.g. different bond connections between atoms).
  - We need an anisotropic mechanism that is independent of the node parametrization.
  - Edge degrees[3]/Edge gates[4]/Attention mechanism[5] : MoNets[3], GAT[5], GatedGCNs[4] can treat neighbors differently.



Isotropic weights



Anisotropic weights

[4] X Bresson, T Laurent, Residual gated graph convnets, 2017
[5] Velickovic, Cucurull, Casanova, Romero, Lio, Bengio, Graph Attention Networks, 2018

MoNets[1]

- MoNets[1] leverage the Bayesian Gaussian Mixture Model (GMM)[2].

$$h_i^{\ell+1}_{d\times 1} = \mathrm{ReLU}\Big(\sum_{k=1}^{K}\sum_{j\in\mathcal{N}_i} \underbrace{e_{ij}^{k,\ell}}_{\text{scalar}}\ \underbrace{W_1^{k,\ell}}_{d\times d}\ \underbrace{h_j^{\ell}}_{d\times 1}\Big)$$

$$\underbrace{e_{ij}^{k,\ell}}_{\text{scalar}} = \exp\Big(-\frac{1}{2}\underbrace{(u_{ij}^{\ell}-\mu_k^{\ell})^T}_{1\times 2}\underbrace{(\Sigma_k^{\ell})^{-1}}_{2\times 2}\underbrace{(u_{ij}^{\ell}-\mu_k^{\ell})}_{2\times 1}\Big)$$

$$\underbrace{u_{ij}^{\ell}}_{2\times 1} = \mathrm{Tanh}\Big(\underbrace{A^{\ell}}_{2\times 2}\ \underbrace{(\deg_i^{-1/2},\deg_j^{-1/2})}_{2\times 1} + \underbrace{a^{\ell}}_{2\times 1}\Big)$$

[2] A. Dempster, NM Laird, D. Rubin, Maximum Likelihood from Incomplete Data Via the EM Algorithm, 1977

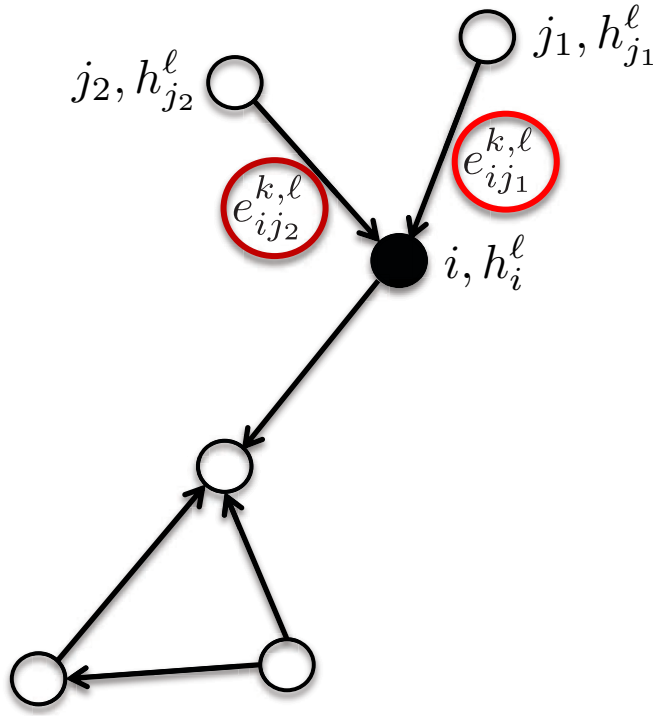
Graph Attention Networks[1] (GAT)

- GAT uses the attention mechanism[2] to introduce anisotropy in the neighborhood aggregation function.
- The network employs a multi-headed architecture to increase the learning capacity, similar to the Transformer[3].

$$h_i^{\ell+1}_{d\times 1} = \text{Concat}_{k=1}^{K}\Big(\text{ELU}\Big(\sum_{j\in\mathcal{N}_i} e_{ij}^{k,\ell}_{\text{scalar}}\ W_1^{k,\ell}_{\frac{d}{K}\times d}\ h_j^{\ell}_{d\times 1}\Big)\Big)$$

$$e_{ij}^{k,\ell}_{\text{scalar}} = \text{Softmax}_{\mathcal{N}_i}(\hat{e}_{ij}^{k,\ell}) = \frac{\exp(\hat{e}_{ij}^{k,\ell})}{\sum_{j'\in\mathcal{N}_i}\exp(\hat{e}_{ij'}^{k,\ell})}$$

$$\hat{e}_{ij}^{k,\ell} = \text{LeakyReLU}\Big(W_2^{k,\ell}_{1\times\frac{2d}{K}}\ \underbrace{\text{Concat}\big(W_1^{k,\ell}h_i^{\ell},\ W_1^{k,\ell}h_j^{\ell}\big)}_{\frac{2d}{K}\times 1}\Big)$$



[1] Velickovic, Cucurull, Casanova, Romero, Lio, Bengio, Graph Attention Networks, 2018

[3] A Vaswani, N Shazeer, N Parmar, J Uszkoreit, L Jones, A. Gomez, L. Kaiser, I. Polosukhin, Attention is all you need, 2017

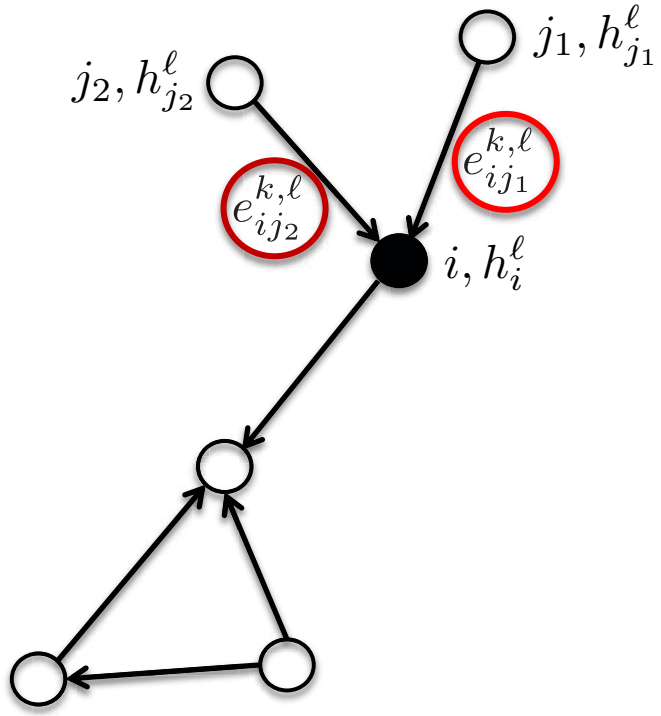
Gated Graph ConvNets[1]

- GatedGCNs use edge gates to design an anisotropic variant of GCNs.
  - Edge gates can be regarded as a soft attention process, related to the standard sparse attention mechanism[2].
  - Edge features are explicit (important for edge prediction tasks).
- Residual connections and batch normalization enhance learning speed and generalization.

$$h_i^{\ell+1}_{d\times 1} = h_i^\ell + \mathrm{ReLU}\Big(\mathrm{BN}\Big(\underset{d\times d}{W_1^\ell}\underset{d\times 1}{h_i^\ell} + \sum_{j\in\mathcal{N}_i}\underset{d\times 1}{e_{ij}^\ell}\odot\underset{d\times d}{W_2^\ell}\underset{d\times 1}{h_j^\ell}\Big)\Big)$$

$$e_{ij}^\ell{}_{d\times 1} = \frac{\sigma(\hat{e}_{ij}^\ell)}{\sum_{j'\in\mathcal{N}_i}\sigma(\hat{e}_{ij'}^\ell)+\varepsilon}$$

$$\hat{e}_{ij}^\ell{}_{d\times 1} = \hat{e}_{ij}^{\ell-1} + \mathrm{ReLU}\Big(\mathrm{BN}\big(\underset{d\times d}{V_1^\ell}h_i^{\ell-1} + \underset{d\times d}{V_2^\ell}h_j^{\ell-1} + \underset{d\times d}{V_3^\ell}\hat{e}_{ij}^{\ell-1}\big)\Big)$$



[1] X Bresson, T Laurent, Residual gated graph convnets, 2017
[2] D Bahdanau, K Cho, Y Bengio, Neural machine translation by jointly learning to align and translate, 2014

Graph Transformers

- Graph version of Transformer[1] :

$$h_i^{\ell+1} = W^{\ell} \; \mathrm{Concat}_{k=1}^{K} \Big(\sum_{j \in \mathcal{N}_i} e_{ij}^{k,\ell} \; V^{k,\ell} \; h_j^{\ell} \Big)$$

$h_i^{\ell+1}$: $d \times 1$; W^{ℓ}: $d \times d$; $V^{k,\ell}$: $\frac{d}{K} \times d$; $e_{ij}^{k,\ell}$: scalar

Value

$$e_{ij}^{k,\ell} = \mathrm{Softmax}_{\mathcal{N}_i}(\hat{e}_{ij}^{k,\ell}) = \frac{\exp(\hat{e}_{ij}^{k,\ell})}{\sum_{j' \in \mathcal{N}_i} \exp(\hat{e}_{ij'}^{k,\ell})}$$

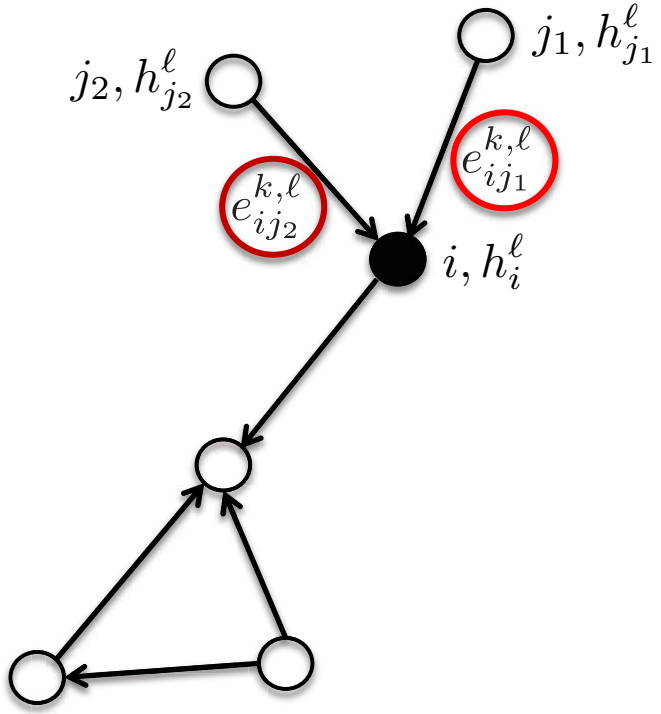
$$\hat{e}_{ij}^{k,\ell} = \big(Q^{\ell,k} h_i^{\ell} \big)^T \big(K^{\ell,k} h_j^{\ell} \big)$$

$Q^{\ell,k} h_i^{\ell}$: $1 \times d$; $K^{\ell,k} h_j^{\ell}$: $d \times 1$

Query

Key

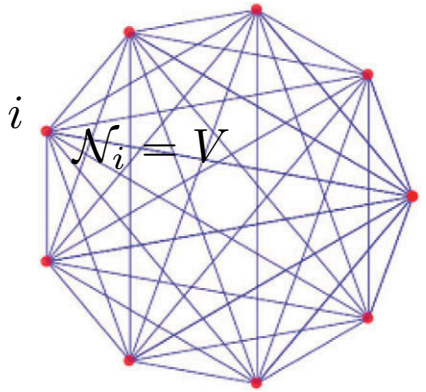
Attention mechanism in 1-hop neighborhood



[1] A Vaswani, N Shazeer, N Parmar, J Uszkoreit, L Jones, A. Gomez, L. Kaiser, I. Polosukhin, Attention is all you need, 2017

Transformers[1]

- Transformers[1] is a special case of GCNs when the graph is fully connected.
- The neighborhood $\mathcal{N}_i$ is the whole graph.



Fully connected graph

$$h_i^{\ell+1} = W^\ell \ \text{Concat}_{k=1}^{K}\Big(\sum_{j \in \mathcal{N}_i} e_{ij}^{k,\ell} \ V^{k,\ell} \ h_j^\ell \Big)$$

$$e_{ij}^{k,\ell} = \text{Softmax}_{\mathcal{N}_i}(\hat{e}_{ij}^{k,\ell}) = \frac{\exp(\hat{e}_{ij}^{k,\ell})}{\sum_{j' \in \mathcal{N}_i} \exp(\hat{e}_{ij'}^{k,\ell})}$$

$$\hat{e}_{ij}^{k,\ell} = (Q^{\ell,k} h_i^\ell)^T (K^{\ell,k} h_j^\ell)$$

$$\mathcal{N}_i = V \Longrightarrow$$

$$\underset{n \times d}{h^{\ell+1}} = \text{Concat}_{k=1}^{K}\Big(\text{Softmax}(Q^\ell {K^\ell}^T) V^\ell\Big) \overset{d \times d}{W^\ell}$$

$$Q^\ell = h^\ell \ W_Q^\ell$$

$$K^\ell = h^\ell \ W_K^\ell$$

$$V^\ell = h^\ell \ W_V^\ell$$

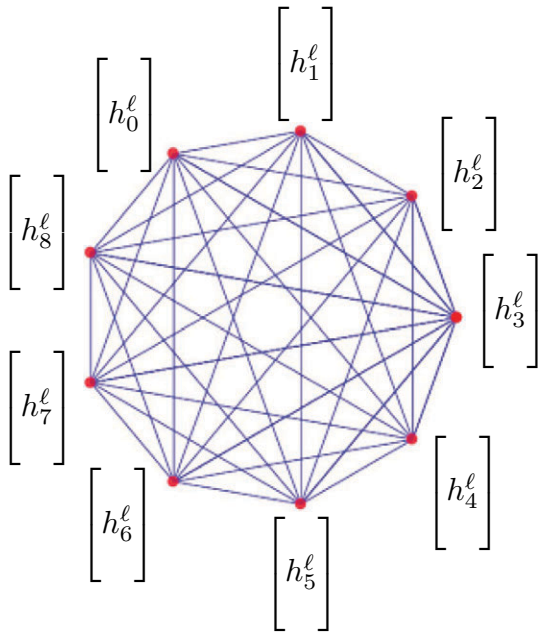
$$\underset{n \times \frac{d}{K}}{Q^\ell} \quad \underset{n \times d}{h^\ell} \quad \underset{d \times \frac{d}{K}}{W_Q^\ell}$$

$$\underbrace{\underbrace{n \times \frac{d}{K} \quad \frac{d}{K} \times n}_{n \times n} \quad n \times \frac{d}{K}}_{n \times \frac{d}{K}}$$

[1] A Vaswani, N Shazeer, N Parmar, J Uszkoreit, L Jones, A. Gomez, L. Kaiser, I. Polosukhin, Attention is all you need, 2017

Transformers

- What does it mean to have a graph fully connected?
  - It becomes less useful to talk about graphs as each data point is connected to all other points. There is no particular graph structure that can be used.
  - It would be better to talk about sets rather than graphs in this case.
  - Transformers are Set Neural Networks.
    - They are today the best technique to analyze sets/bags of features.



Fully connected graph

$\Leftrightarrow$

h_0^ℓ h_1^ℓ h_2^ℓ h_3^ℓ h_4^ℓ h_5^ℓ h_6^ℓ h_7^ℓ h_8^ℓ

Sets of features

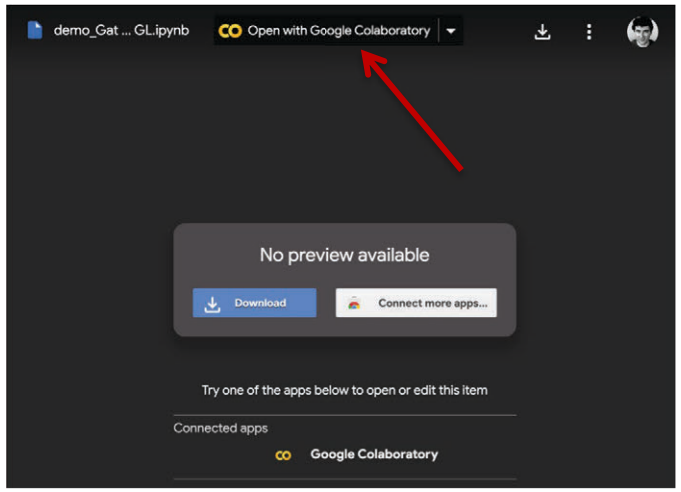
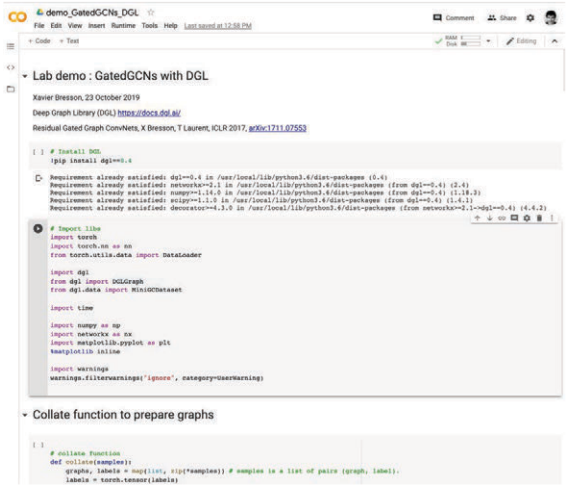
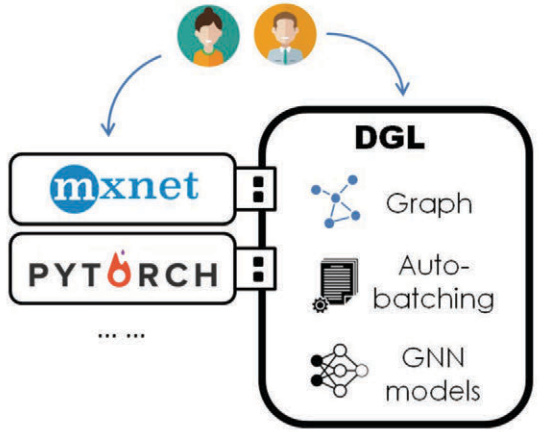
DGL







Lab on GatedGCNs

DGL creates a batch of graphs

Create artificial node feature (input degree) and edge feature (value 1)

```python
# collate function
def collate(samples):
    graphs, labels = map(list, zip(*samples)) # samples is a list of pairs (graph, label).
    labels = torch.tensor(labels)
    tab_sizes_n = [ graphs[i].number_of_nodes() for i in range(len(graphs))] # graph sizes
    tab_snorm_n = [ torch.FloatTensor(size,1).fill_(1./float(size)) for size in tab_sizes_n ]
    snorm_n = torch.cat(tab_snorm_n).sqrt() # normalization constant for better optimization
    tab_sizes_e = [ graphs[i].number_of_edges() for i in range(len(graphs))] # nb of edges
    tab_snorm_e = [ torch.FloatTensor(size,1).fill_(1./float(size)) for size in tab_sizes_e ]
    snorm_e = torch.cat(tab_snorm_e).sqrt() # normalization constant for better optimization
    batched_graph = dgl.batch(graphs) # batch graphs
    return batched_graph, labels, snorm_n, snorm_e

# create artifical data feature (= in degree) for each node
def create_artificial_features(dataset):
    for (graph,_) in dataset:
        graph.ndata['feat'] = graph.in_degrees().view(-1, 1).float()
        graph.edata['feat'] = torch.ones(graph.number_of_edges(),1)
    return dataset

# use artifical graph dataset of DGL
trainset = MiniGCDataset(8, 10, 20)
trainset = create_artificial_features(trainset)
print(trainset[0])
```

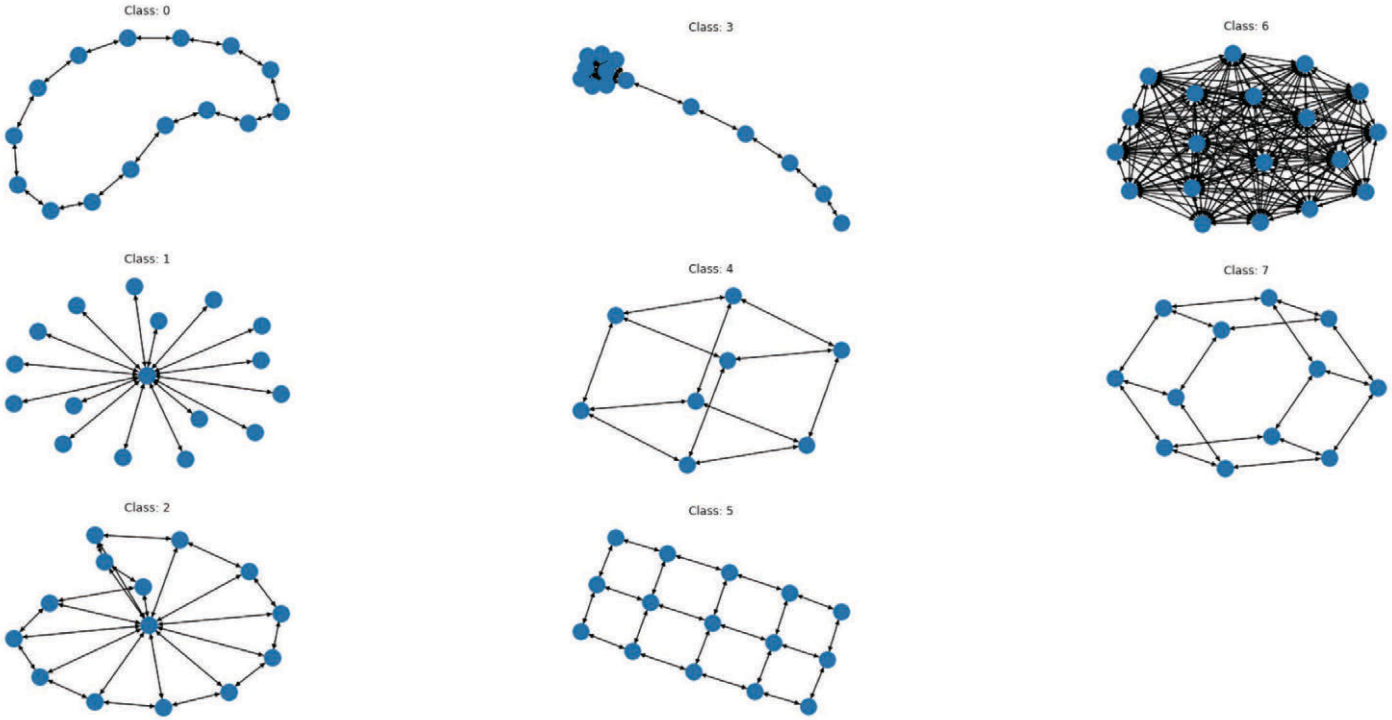
```
(DGLGraph(num_nodes=13, num_edges=39,
          ndata_schemes={'feat': Scheme(shape=(1,), dtype=torch.float32)}
          edata_schemes={'feat': Scheme(shape=(1,), dtype=torch.float32)}), 0)
```

$$\frac{1}{\sqrt{V_k}}, \frac{1}{\sqrt{E_k}}$$

Graph normalization constants

Lab on GatedGCNs

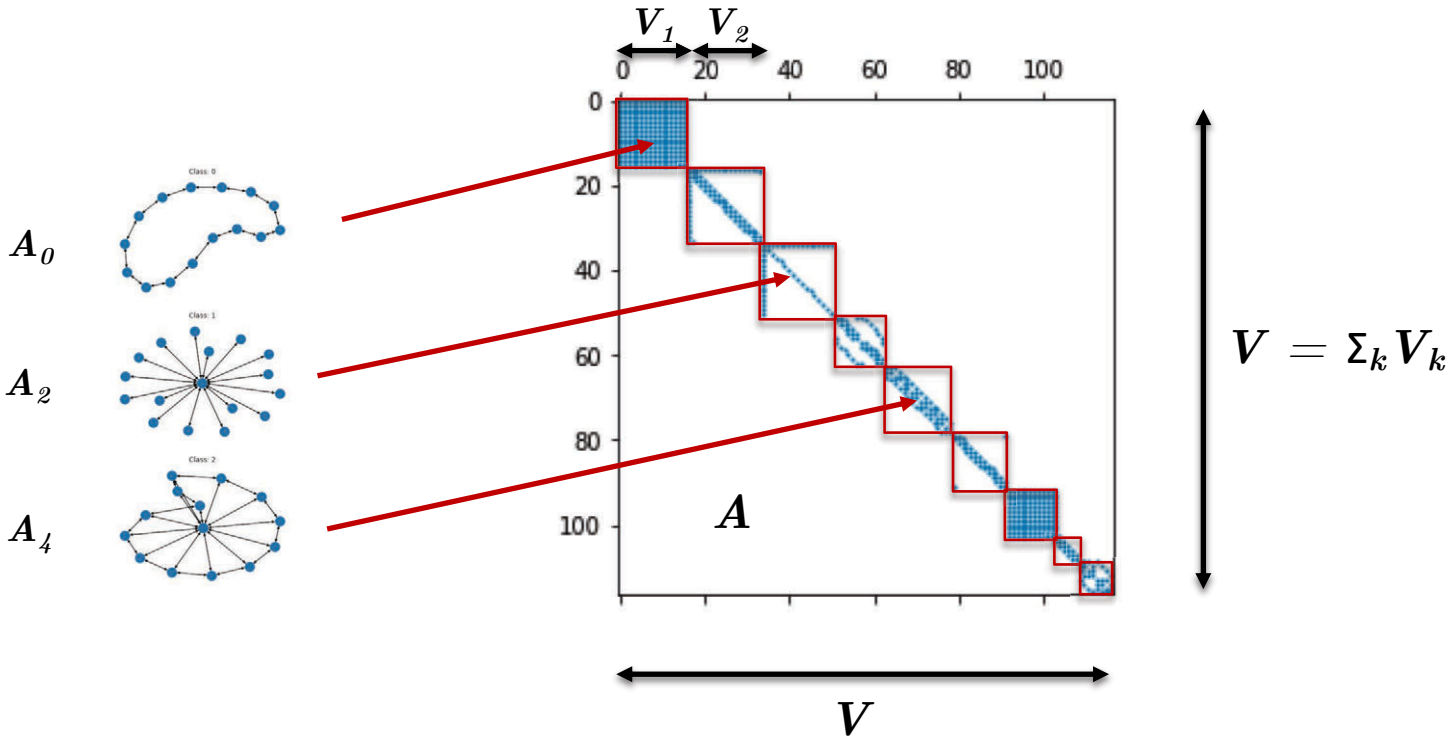
```
# use artifical graph dataset of DGL
trainset = MiniGCDataset(8, 10, 20)
```



Lab on GatedGCNs

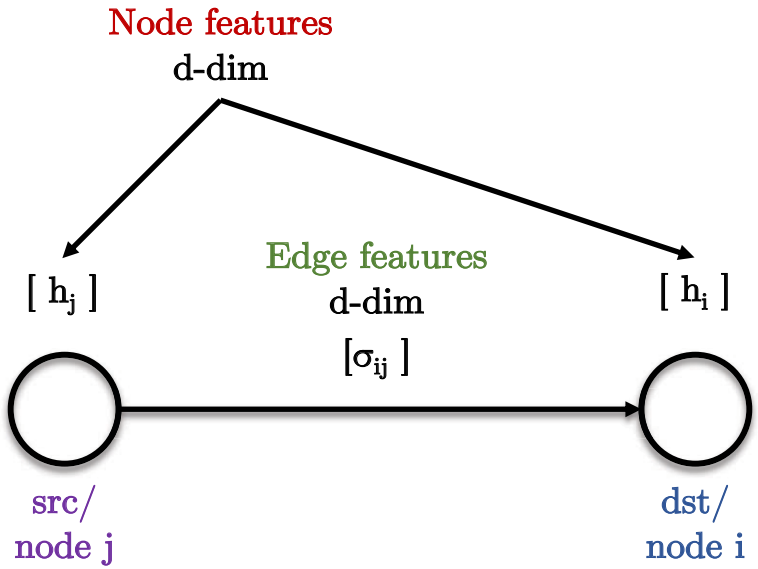
- Understanding DGL :
  - How to process K graphs of different sizes ?

    Form a (big) sparse block diagonal matrix $\boldsymbol{A}$ with K adjacency matrices $\boldsymbol{A}_k$.



Lab on GatedGCNs

- Basic structure of an edge in DGL :

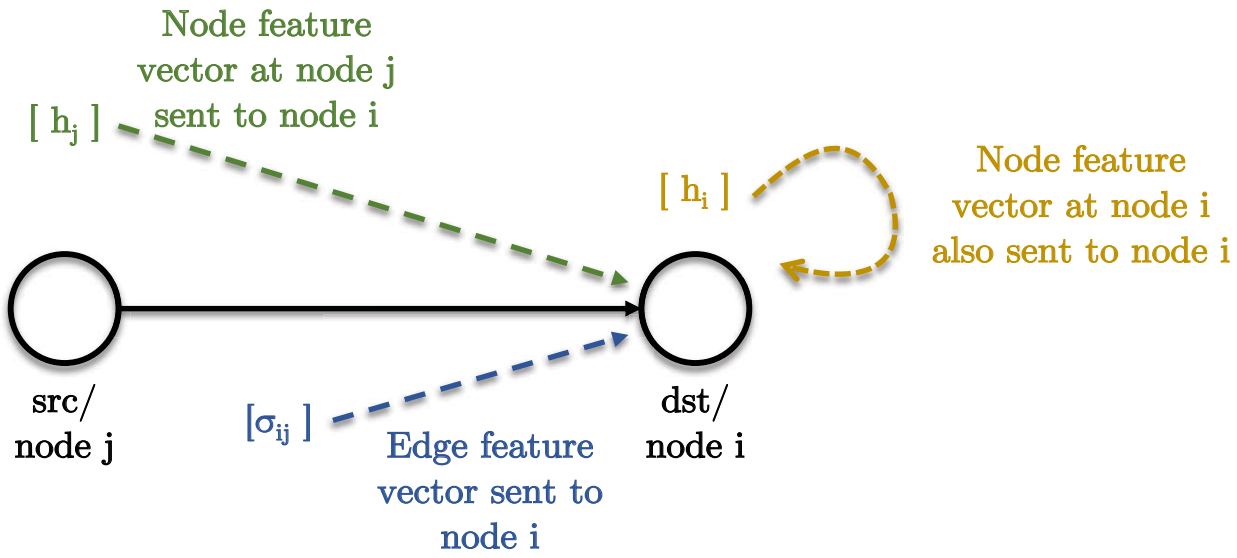


- Goal is to compute efficiently expressions of the form :

$$f_i = h_i + \Sigma_{j \to i}\, \sigma_{ij} \circ h_j$$

Lab on GatedGCNs

- Step 1 : Message passing function defined on edges
  - Node feature and edge feature are passed along all edges connecting a node.



h_j : edges.src['h'] . size() = E x d

h_i : edges.dst['h'] . size() = E x d

σ_{ij} : edges.data['σ'] . size() = E x d

#edges

All message passing operations can be done in parallel !

Lab on GatedGCNs

- Step 2 : Reduce function defined on nodes
  - Reduce functions of the form : $f_i = h_i + \Sigma_{j \to i}\ \sigma_{ij} \circ h_j$
  - Reduce function collects all messages passed in Step 1.
  - Code : $f = h_i$ + torch.sum (h_j x σ_{ij} , dim=1) . size() = V x d

#nodes

Sum over neighbors

- GPU acceleration :
  - DGL batches the nodes with the same number of neighbors.

#nodes in $batch_1$

h_j = nodes.mailbox['h_j'] = [$batch_1$ .size() = 11 x 12 x d ; ⋮ ; $batch_{34}$ .size() = 14 x 9 x d]

#neighbors

σ_{ij} = nodes.mailbox['σ_{ij}'] = same structure than h_j

h_i = nodes.data['h'] . size() = V x d

Lab on GatedGCNs

GatedGCN layer :

$$h_i^{\ell+1} = h_i^\ell + \mathrm{ReLU}\Big(\mathrm{BN}\Big(A^\ell h_i^\ell + \sum_{j\sim i} \eta(e_{ij}^\ell) \odot B^\ell h_j^\ell\Big)\Big)/\sqrt{V_k}.$$

$$\eta(e_{ij}^\ell) = \frac{\sigma(e_{ij}^\ell)}{\sum_{j'\sim i}\sigma(e_{ij'}^\ell) + \varepsilon},$$

$$e_{ij}^{\ell+1} = e_{ij}^\ell + \mathrm{ReLU}\Big(\mathrm{BN}\Big(C^\ell e_{ij}^\ell + D^\ell h_i^{\ell+1} + E^\ell h_j^{\ell+1}\Big)\Big)/\sqrt{E_k}.$$

```python
class GatedGCN_layer(nn.Module):

    def __init__(self, input_dim, output_dim):
        super(GatedGCN_layer, self).__init__()
        self.A = nn.Linear(input_dim, output_dim, bias=True)

        e = e_in + e # residual connection

        return h, e
```

Lab on GatedGCNs

MLP classifier layer

```python
class MLP_layer(nn.Module):

    def __init__(self, input_dim, output_dim, L=2): # L = nb of hidden layers
        super(MLP_layer, self).__init__()
        list_FC_layers = [ nn.Linear( input_dim, input_dim, bias=True ) for l in range(L) ]
        list_FC_layers.append(nn.Linear( input_dim, output_dim , bias=True ))
        self.FC_layers = nn.ModuleList(list_FC_layers)
        self.L = L

    def forward(self, x):
        y = x
        for l in range(self.L):
            y = self.FC_layers[l](y)
            y = F.relu(y)
        y = self.FC_layers[self.L](y)
        return y
```

GatedGCN Network

Node input embedding

Edge input embedding

Run graphNN layers

Compute graph vectorial representation by a (simple) average of all node features with DGL.

Use MLP classifier

```python
class GatedGCN_Net(nn.Module):

    def __init__(self, net_parameters):
        super(GatedGCN_Net, self).__init__()
        input_dim = net_parameters['input_dim']
        hidden_dim = net_parameters['hidden_dim']
        output_dim = net_parameters['output_dim']
        L = net_parameters['L']
        self.embedding_h = nn.Linear(input_dim, hidden_dim)
        self.embedding_e = nn.Linear(1, hidden_dim)
        self.GatedGCN_layers = nn.ModuleList([ GatedGCN_layer(hidden_dim, hidden_dim) for _ in range(L) ])
        self.MLP_layer = MLP_layer(hidden_dim, output_dim)

    def forward(self, g, h, e, snorm_n, snorm_e):

        # input embedding
        h = self.embedding_h(h)
        e = self.embedding_e(e)

        # graph convnet layers
        for GGCN_layer in self.GatedGCN_layers:
            h,e = GGCN_layer(g,h,e,snorm_n,snorm_e)

        # MLP classifier
        g.ndata['h'] = h
        y = dgl.mean_nodes(g,'h')
        y = self.MLP_layer(y)

        return y
```

- Conclusion

Benchmarking GNNs

- Recent release (Mar 2020) of "Benchmarking Graph Neural Networks", V.P. Dwivedi, C. Joshi, T. Laurent, Y. Bengio , X. Bresson, https://arxiv.org/pdf/2003.00982.pdf
- Why this benchmark ?
  - Most published GNN papers use small datasets (CORA and TUs) and one task (classification) for which GNNs (and agnostic-GNNs) have statistically the same performance.
  - How to identify good GNNs ?
  - How to quantify the practical impact of the recent theoretical GNNs ?
  - Benchmarks have been essential to make progresses in many fields like Deep Learning (ImageNet of Prof. F.F. Li). But people are reluctant to give credit to benchmarks.
- We introduced an open benchmark infrastructure for GNNs, hosted on GitHub based on PyTorch and DGL.
  - This benchmark has 6 new medium-scale datasets for the 4 fundamental graph problems (graph classification and regression, node classification and edge classification).
  - These datasets have medium sizes but they are enough to statistically separate trends in GNNs.
  - We make easy for new users to add new GNN models and new datasets.
  - GitHub repo (600*) : https://github.com/graphdeeplearning/benchmarking-gnns

GNN Pipeline

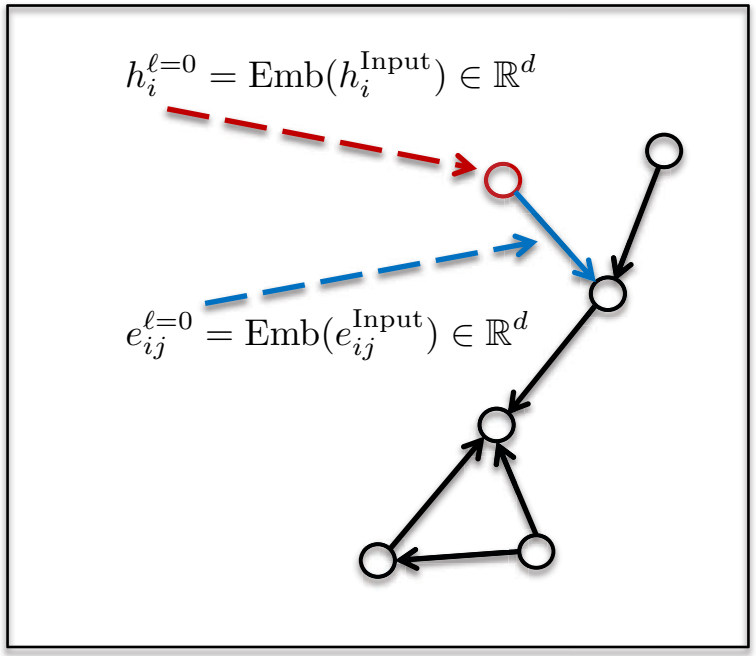
- Standard GNN pipeline :
  - Input layer : Linear embedding of input node/edge features.
  - GNN layers : Apply favorite GNN layer L times.
  - Task-based layer : Graph/node/edge prediction layer.

GNN Pipeline

- Input layer :

$$h^{\text{Input}}$$
$$e^{\text{Input}}$$

$\Rightarrow$



$\Rightarrow$

$$h^{\ell=0} \in \mathbb{R}^{n \times d}$$
$$e^{\ell=0} \in \mathbb{R}^{E \times d}$$

Input node/edge features

Embedding layer of input features

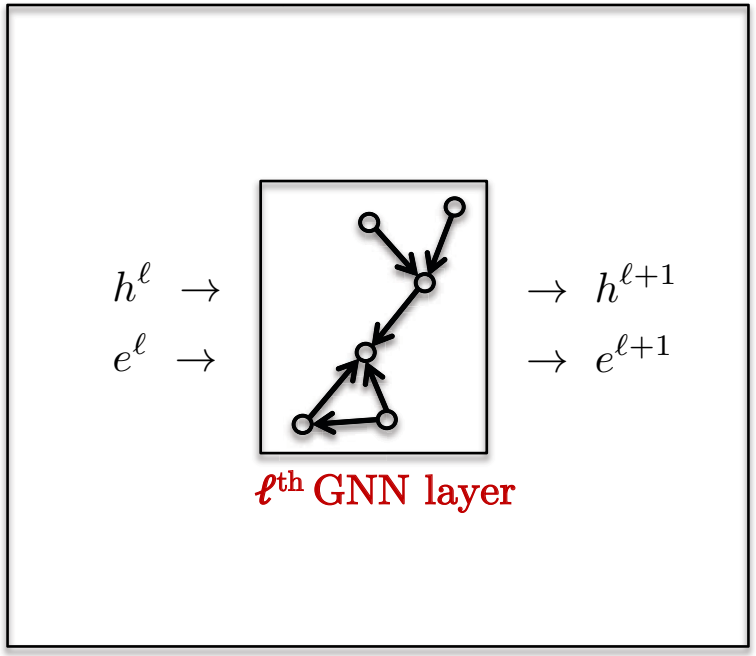
Input features embedded into d-dim spaces, and passes to the GNN layers.

GNN Pipeline

- GNN layers :

$$h^{\ell=0} \in \mathbb{R}^{n \times d}$$
$$e^{\ell=0} \in \mathbb{R}^{E \times d}$$

$\Rightarrow$



$\Rightarrow$

$$h^{\ell=L} \in \mathbb{R}^{n \times d}$$
$$e^{\ell=L} \in \mathbb{R}^{E \times d}$$

Input of GNNs indexed by $\ell=0$.

GNN layers applied L times

Output of GNNs indexed by $\ell=L$.

GNN Pipeline

- Task-based layer
  - Graph-level prediction :

$$h^{\mathcal{G}} = \frac{1}{n}\sum_{i=0}^{n} h_i^{\ell=L} \in \mathbb{R}^d \quad \Rightarrow \quad \boxed{\text{MLP}} \quad \Rightarrow \quad \text{score} \in \begin{cases} \mathbb{R} & \text{regression} \\ \mathbb{R}^K, \ K>1 & \text{classification} \end{cases}$$

  - Node-level prediction :

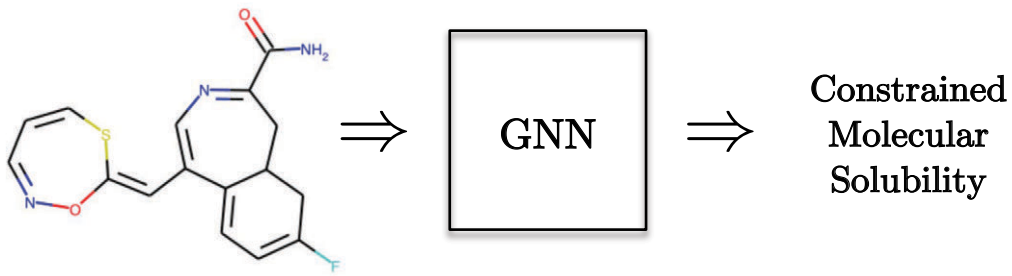
$$h_i^{\ell=L} \in \mathbb{R}^d \quad \Rightarrow \quad \boxed{\text{MLP}} \quad \Rightarrow \quad \text{score}_i \in \begin{cases} \mathbb{R} & \text{regression} \\ \mathbb{R}^K, \ K>1 & \text{classification} \end{cases}$$

  - Edge-level prediction :

$$e_{ij}^{\text{link}} = \text{Concat}(h_i^{\ell=L}, h_j^{\ell=L}) \in \mathbb{R}^d \quad \Rightarrow \quad \boxed{\text{MLP}} \quad \Rightarrow \quad \text{score}_{ij} \in \begin{cases} \mathbb{R} & \text{regression} \\ \mathbb{R}^K, \ K>1 & \text{classification} \end{cases}$$

Quantum Chemistry

- Graph regression task. We used the ZINC dataset to regress a molecular property known as the constrained solubility [Jin et al., 2018]. Statistics : 10,000 train/1,000 validation/1,000 test graphs of sizes 9-37 nodes/atoms.



Model	#Param	Acc/MAE	Epoch/Total
MLP	108975	0.710±0.001	1.19s/0.02hr
MLP (Gated)	106970	0.681±0.005	1.16s/0.03hr

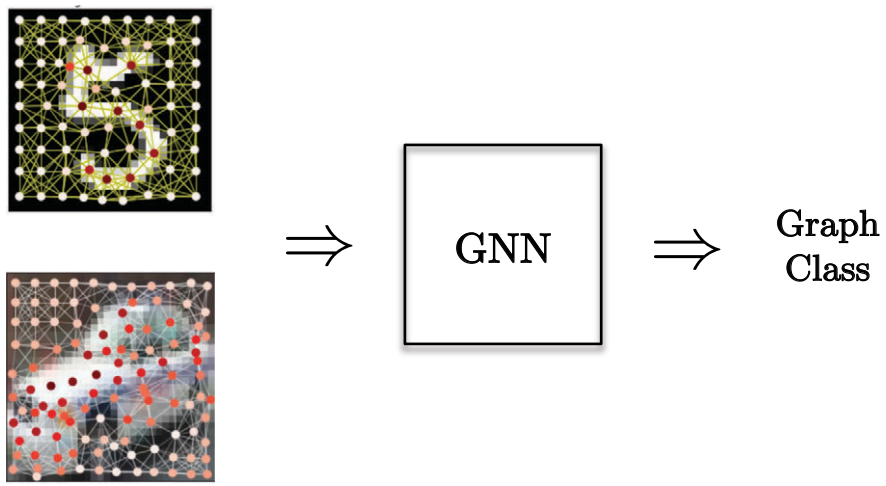
GIN	103079	0.414±0.009	2.49s/0.06hr
DiffPool	110561	0.466±0.006	12.41s/0.34hr
GAT	102385	0.463±0.002	20.97s/0.56hr
MoNet	106002	0.407±0.007	11.69s/0.28hr
GatedGCN	105735	0.437±0.008	6.36s/0.17hr

Computer Vision

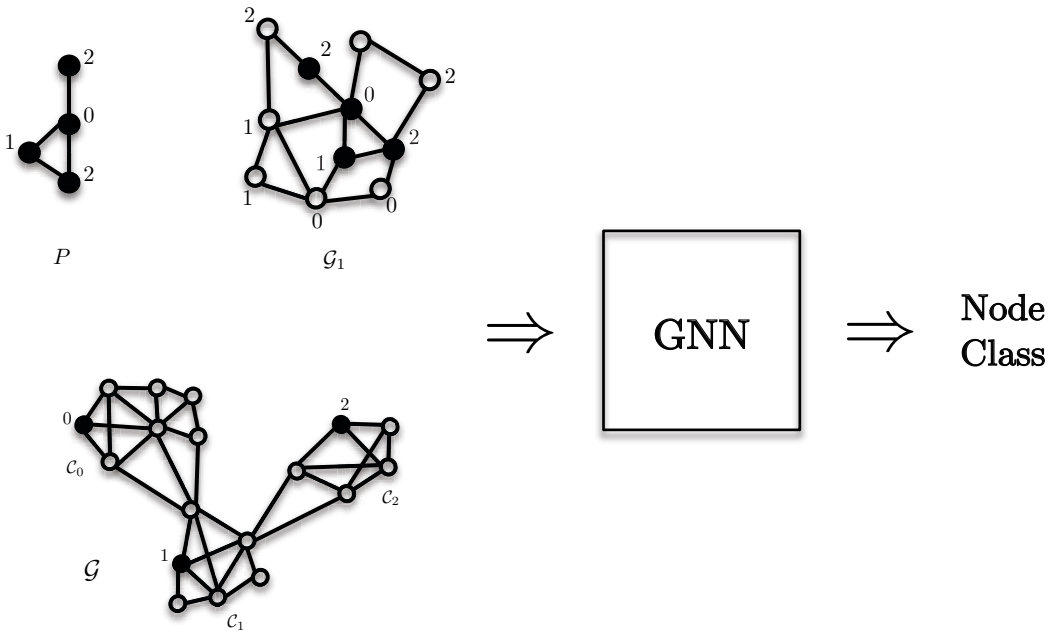
- Graph classification task. We used popular MNIST and CIFAR10 image datasets. Images are converted to graphs using super-pixels [Achanta et al., 2012]. MNIST has 55,000 train/5,000 validation/10,000 test graphs of sizes 40-75 nodes and CIFAR10 has 45,000 train/5,000 validation/10,000 test graphs of sizes 85-150 nodes.



Dataset	Model	#Param	Acc	Epoch/Total
MNIST	MLP	104044	94.46±0.28	21.82s/1.02hr
	MLP (Gated)	105717	95.18±0.18	22.43s/0.73hr
	GCN	101365	89.99±0.15	78.25s/1.81hr
	GraphSage	102691	97.09±0.02	75.57s/1.36hr
	GIN	105434	93.91±0.63	34.30s/0.73hr
	DiffPool	106538	95.02±0.42	170.55s/4.26hr
	GAT	110400	95.62±0.13	375.71s/6.35hr
	MoNet	104049	90.36±0.47	581.86s/15.31hr
	GatedGCN	104217	97.37±0.06	128.39s/2.01hr
CIFAR10	MLP	104044	56.01±0.90	21.82s/1.02hr
	MLP (Gated)	106017	56.78±0.12	27.85s/0.68hr
	GCN	101657	54.46±0.10	100.91s/2.73hr
	GraphSage	102907	65.93±0.30	96.67s/1.88hr
	GIN	105654	53.28±3.70	45.29s/1.24hr
	DiffPool	108042	57.99±0.45	298.06s/10.17hr
	GAT	110704	65.40±0.38	389.40s/7.32hr
	MoNet	104229	53.42±0.43	836.32s/22.45hr
	GatedGCN	104357	69.19±0.28	146.80s/2.48hr

Stochastic Block Models

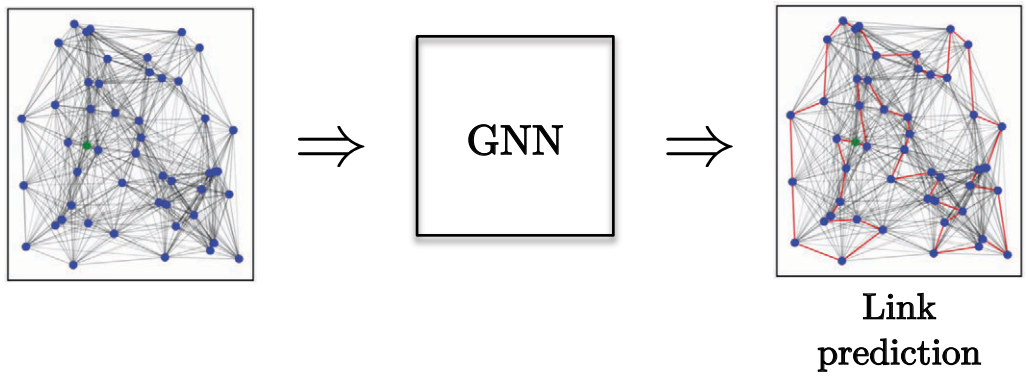
- Node classification task. We used the stochastic block model to generate graph patterns embedded in larger graphs (PATTERN dataset) and generate clusters with variable sizes (CLUSTER dataset). Statistics : PATTERN has 10,000 train/2,000 validation/2,000 test graphs of sizes 50-180 nodes. CLUSTER has 10,000 train/1,000 validation/1,000 test graphs of sizes 40-190 nodes.



Dataset	Model	#Param	Acc	Epoch/Total
PATTERN	MLP	105263	50.13±0.00	8.68s/0.10hr
	MLP (Gated)	103629	50.13±0.00	9.78s/0.12hr
	GCN	100923	74.36±1.59	97.37s/2.06hr
	GraphSage	98607	78.20±3.06	79.19s/2.57hr
	GIN	100884	96.98±2.18	14.12s/0.32hr
	GAT	109936	90.72±2.04	229.76s/5.73hr
	MoNet	103775	95.52±3.74	879.87s/21.80hr
	GatedGCN	104003	95.05±2.80	115.55s/2.46hr
CLUSTER	MLP	106015	20.97±0.01	6.54s/0.08hr
	MLP (Gated)	104305	20.97±0.01	7.37s/0.09hr
	GCN	101655	47.82±4.91	66.58s/1.26hr
	GraphSage	99139	44.89±3.70	54.53s/1.05hr
	GIN	103544	49.64±2.09	11.60s/0.27hr
	GAT	110700	49.08±6.47	158.23s/4.08hr
	MoNet	104227	45.95±3.39	635.77s/15.32hr
	GatedGCN	104355	54.20±3.58	81.39s/2.26hr

Combinatorial Optimization

- Edge classification task. We used the Travelling Salesman Problem (TSP). Given a 2D graph, find a tour with minimal length. Statistics : We create train, validation and test sets of 10,000 train TSP / 1,000 TSP / 1,000 TSP, where the number of nodes is randomly selected in [50, 500].



Model	#Param	F1	Epoch/Total
k-NN Heuristic	k=2	F1: 0.693	
MLP	94394	0.548±0.003	53.92s/2.85hr
MLP (Gated)	115274	0.548±0.001	54.39s/2.44hr
GCN	108738	0.627±0.003	163.36s/11.26hr
GraphSage	98450	0.663±0.003	145.75s/16.05hr
GIN	118574	0.655±0.001	73.09s/5.44hr
GAT	109250	0.669±0.001	360.92s/30.38hr
MoNet	94274	0.637±0.010	1433.97s/41.69hr
GatedGCN	94946	0.794±0.004	203.28s/15.47hr

Workshop Announcement

ORGANIZING COMMITTEE

Peter Battaglia (DeepMind Technologies)

Xavier Bresson (Nanyang Technological University, Singapore)

Stefanie Jegelka (Massachusetts Institute of Technology)

Yann LeCun (New York University, Canadian Institute for Advanced Research)

Andrea Lodi (École Polytechnique de Montréal)

Stanley Osher (University of California, Los Angeles (UCLA), Mathematics)

Oriol Vinyals (Google)

Max Welling (Universiteit van Amsterdam)

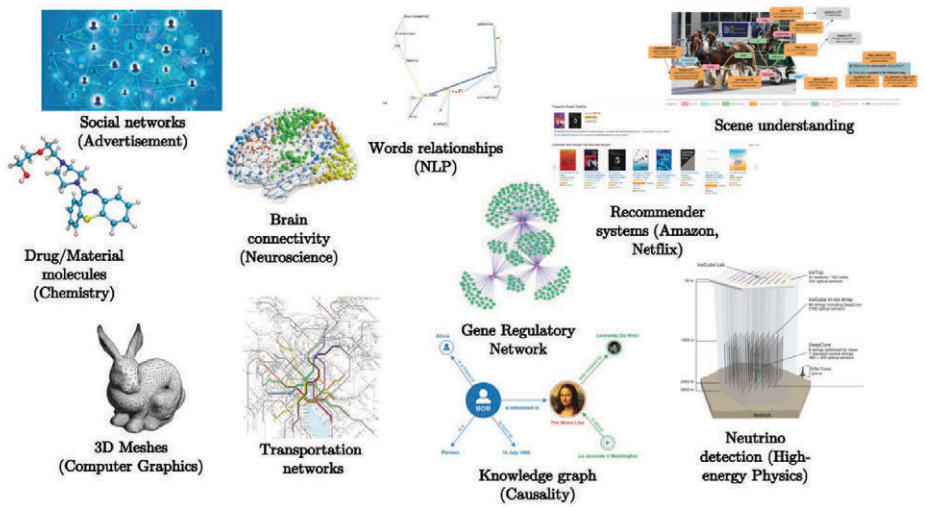
Outline

- Part 1: Traditional ConvNets
  - Architecture
  - Graph Domain
  - Convolution
- Part 2: Spectral Graph ConvNets
  - Spectral Convolution
  - Spectral GCNs
- Part 3: Spatial Graph ConvNets
  - Template Matching
  - Isotropic GCNs
  - Anisotropic GCNs
  - Lab on GatedGCNs
- Part 4: Benchmarking Graph Neural Networks
- **Conclusion**

Conclusion

- Contributions :
  - Generalization of ConvNets to data on graphs
  - Re-design convolution operator on graphs
  - Linear complexity for sparse graphs
  - GPU implementation (not yet optimized for sparse matrix-matrix multiplications)
  - Universal learning capacity
  - Multiple and dynamic graphs

- Applications :



"Graphs are the most important discrete models in the world!" - G. Strang (MIT)

Tutorials on Graph Deep Learning

SIAM Annual Meeting'18

NeurIPS'17
1,000-2,000 participants

CVPR'17
500-1,000 participants

New Deep Learning Techniques

FEBRUARY 5 - 9, 2018

OVERVIEW | SPEAKER LIST | SCHEDULE | APPLY/REGISTER

Overview

In recent years, artificial neural networks a.k.a. deep learning have significantly improved the fields of computer vision, speech recognition, and natural language processing. The success relies on the availability of large-scale datasets, the developments of affordable high computational power, and basic deep learning operations that are sound and fast as they assume that data lie on Euclidean grids. However, not all data live on regular lattices. 3D shapes in computer graphics represent Riemannian manifolds. In neuroscience, brain activity (fMRI) is encoded on the structural connectivity network (sMRI). In genomics, the human body functionality is expressed through DNA, RNA, and proteins that form the gene regulatory network (GRN). In social sciences, people interact through networks. Eventually, data in communication networks are structured by graphs like the Internet or road traffic networks.

Deep learning that has originally been developed for computer vision cannot be directly applied to these highly irregular domains, and new classes of deep learning techniques must be designed. This is highly challenging as most standard data analysis tools cannot be used on heterogonous data domains. The workshop will bring together experts in mathematics (statistics, harmonic analysis, optimization, graph theory, sparsity, topology), machine learning (deep learning, supervised & unsupervised learning, metric learning) and specific applicative domains (neuroscience, genetics, social science, computer vision) to establish the current state of these emerging techniques and discuss the next directions.

This workshop will include a poster session; a request for posters will be sent to registered participants in advance of the workshop.

Workshop IV: Deep Geometric Learning of Big Data and Applications

Part of the Long Program Geometry and Learning from Data in 3D and Beyond

MAY 20 - 24, 2019

OVERVIEW | SPEAKER LIST | SCHEDULE | APPLY/REGISTER

Overview

Deep learning techniques have achieved impressive performance in computer vision, natural language processing and speech analysis. These tasks focus on data that lie on Euclidean domains, and mathematical tools for these domains, such as convolution, downsampling, multi-scale, and locality, are well-defined and benefit from fast computational hardware like GPUs. However, many essential data and tasks deal with non-Euclidean domains for which deep learning methods were not originally designed. Examples include 3D point clouds and 3D shapes in computer graphics, functional MRI signals on the brain structural connectivity network, the DNA of the gene regulatory network in genomics, drugs design in quantum chemistry, neutrino detection in high energy physics, and knowledge graph for common sense understanding of visual scenes. This major limitation has pushed the research community in recent years to generalize neural networks to arbitrary geometric domains like graphs and manifolds. Fundamental operations such as convolution, coarsening, multi-resolution, causality have been redefined through spectral and spatial approaches. Recent results for these non-Euclidean data analysis problems show promising and exciting new tools for applications in many fields.

The goals of this workshop are to 1) bring together mathematicians, machine learning scientists and domain experts to establish the current state of these emerging techniques, 2) discuss a framework for the analysis of these new deep learning techniques, 3) establish new research directions and applications of these techniques in neuroscience, social science, computer vision, natural language processing, physics, chemistry, and 4) discuss new computer processing architecture beyond GPU adapted to non-Euclidean domains.

This workshop will include a poster session; a request for posters will be sent to registered participants in advance of the workshop.
